New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York

Chapter 1

Credits

Axiom has a very long history and many people have contributed to the effort, some in large ways and some in small ways. Any and all effort deserves recognition. There is no other criteria than contribution of effort. We would like to acknowledge and thank the following people:

Chapter 2

The Interpreter

The Axiom interpreter is a large common lisp program. It has several forms of interaction and run from terminal in a standalone fashion, run under the control of a session handler program, run as a web server, or run in a unix pipe.

Chapter 3

The Fundamental Data Structures

Axiom currently depends on a lot of global variables. These are generally listed here along with explanations.

3.1 The global variables

3.1.1 defvar \$current-directory

The `$current-directory` variable is set to the current directory at startup. This is used by the `)cd` function and some of the compile routines. This is the result of the (p36) `get-current-directory` function. This variable is used to set `*default-pathname-defaults*`. The (p40) `reroot` function resets it to `$spadroot`.

An example of a runtime value is:

```
$current-directory = "/research/test/"
```

3.1.2 defvar \$current-directory

— initvars —

```
(defvar $current-directory nil)
```

—————

3.1.3 defvar \$defaultMsgDatabaseName

The `$defaultMsgDatabaseName` variable contains the location of the international message database. This can be changed to use a translated version of the messages. It defaults to the United States English version. The relative pathname used as the default is hardcoded in the (p40) `reroot` function. This value is prefixed with the `$spadroot` to make the path absolute.

In general, all Axiom message text should be stored in this file to enable internationalization of messages.

An example of a runtime value is:

```
|$defaultMsgDatabaseName| =
  #p"/research/test/mnt/ubuntu/doc/messages/s2-us.messages"
```

3.1.4 defvar \$defaultMsgDatabaseName

— initvars —

```
(defvar |$defaultMsgDatabaseName| nil)
```

—

3.1.5 defvar \$directory-list

The `$directory-list` is a runtime list of absolute pathnames. This list is generated by the (p40) `reroot` function from the list of relative paths held in the variable `$relative-directory-list`. Each entry will be prefixed by `$spadroot`.

An example of a runtime value is:

```
$directory-list =
  ("/research/test/mnt/ubuntu/../../src/input/"
   "/research/test/mnt/ubuntu/doc/messages/"
   "/research/test/mnt/ubuntu/../../src/algebra/"
   "/research/test/mnt/ubuntu/../../src/interp/"
   "/research/test/mnt/ubuntu/doc/spadhelp/")
```

3.1.6 defvar \$directory-list

— initvars —

```
(defvar $directory-list nil)
```

3.1.7 defvar \$InitialModemapFrame

The `$InitialModemapFrame` is used as the initial value.

See the function “makeInitialModemapFrame” (5.3.14 p 37).

An example of a runtime value is:

```
$InitialModemapFrame = '((nil))
```

3.1.8 defvar \$InitialModemapFrame

— initvars —

```
(defvar |$InitialModemapFrame| '((nil)))
```

3.1.9 defvar \$library-directory-list

The `$library-directory-list` variable is the system-wide search path for library files. It is set up in the (p40) reroot function by prepending the `$spadroot` variable to the `$relative-library-directory-list` variable.

An example of a runtime value is:

```
$library-directory-list = ("/research/test/mnt/ubuntu/algebra/")
```

3.1.10 defvar \$library-directory-list

— initvars —

```
(defvar $library-directory-list '("/algebra/"))
```

3.1.11 defvar \$msgDatabaseName

The `$msgDatabaseName` is a locally shared variable among the message database routines.

An example of a runtime value is:

```
|$msgDatabaseName| = nil
```

3.1.12 defvar \$msgDatabaseName

— initvars —

```
(defvar |$msgDatabaseName| nil)
```

—————

3.1.13 defvar \$openServerIfTrue

The `$openServerIfTrue` It appears to control whether the interpreter will be used as an open server, probably for OpenMath use.

If an open server is not requested then this variable to NIL

See the function “openserver” (64.0.23 p 985).

An example of a runtime value is:

```
$openServerIfTrue = nil
```

3.1.14 defvar \$openServerIfTrue

— initvars —

```
(defvar $openServerIfTrue nil)
```

—————

3.1.15 defvar \$relative-directory-list

The `$relative-directory-list` variable contains a hand-generated list of directories used in the Axiom system. The relative directory list specifies a search path for files for the current directory structure. It has been changed from the NAG distribution back to the original form.

This list is used by the (p40) reroot function to generate the absolute list of paths held in the variable `$directory-list`. Each entry will be prefixed by `$spadroot`.

An example of a runtime value is:

```
$relative-directory-list =
  ("../../../../src/input/"
   "/doc/msgs/"
   "../../../../src/algebra/"
   "../../../../src/interp/"
   "/doc/spadhelp/")
```

3.1.16 defvar \$relative-directory-list

— initvars —

```
(defvar $relative-directory-list
  '("../../../../src/input/"
    "/doc/msgs/"
    "../../../../src/algebra/"
    "../../../../src/interp/" ; for lisp files (helps fd)
    "/doc/spadhelp/" ))
```

3.1.17 defvar \$relative-library-directory-list

The `$relative-library-directory-list` is a hand-generated list of directories containing algebra. The (p40) `reroot` function will prefix every path in this list with the value of the `$spadroot` variable to construct the `$library-directory-list` variable.

An example of a runtime value is:

```
$relative-library-directory-list = ("/algebra/")
```

3.1.18 defvar \$relative-library-directory-list

— initvars —

```
(defvar $relative-library-directory-list '("/algebra/"))
```

3.1.19 defvar \$spadroot

The `$spadroot` variable is the internal name for the AXIOM shell variable. It is set in `reroot` to the value of the argument. The value is expected to be a directory name. The (p35)

initroot function uses this variable if the AXIOM shell variable is not set. The (p36) make-absolute-filename function uses this path as a prefix to all of the relative filenames to make them absolute.

An example of a runtime value is:

```
$spadroot = "/research/test/mnt/ubuntu"
```

3.1.20 defvar \$spadroot

— initvars —

```
(defvar $spadroot nil)
```

—————

3.1.21 defvar \$SpadServer

The `$SpadServer` determines whether Axiom acts as a remote server.

See the function “openserver” (64.0.23 p 985).

An example of a runtime value is:

```
$SpadServer = nil
```

3.1.22 defvar \$SpadServer

— initvars —

```
(defvar $SpadServer nil "t means Axiom acts as a remote server")
```

—————

3.1.23 defvar \$SpadServerName

The `$SpadServerName` defines the name of the spad server socket. In unix these exist in the tmp directory as names.

See the function “openserver” (64.0.23 p 985).

An example of a runtime value is:

```
$SpadServerName = "/tmp/.d"
```

3.1.24 defvar \$SpadServerName

— initvars —

```
(defvar $SpadServerName "/tmp/.d" "the name of the spad server socket")
```

—————

Chapter 4

Starting Axiom

Axiom starts by invoking a function value of the lisp symbol `*top-level-hook*`. The function invocation path to from this point until the prompt is approximates (skipping initializations):

```
lisp -> restart
      -> |spad|
      -> |runspad|
      -> |ncTopLevel|
      -> |ncIntLoop|
      -> |intloop|
      -> |SpadInterpretStream|
      -> |intloopReadConsole|
```

The `—intloopReadConsole—` function does tail-recursive calls to itself (don't break this) and never exits.

4.1 Variables Used

4.2 Data Structures

4.3 Functions

4.3.1 Set the restart hook

When a lisp image containing code is reloaded there is a hook to allow a function to be called. In our case it is the restart function which is the entry to the Axiom interpreter.

— **defun set-restart-hook 0** —

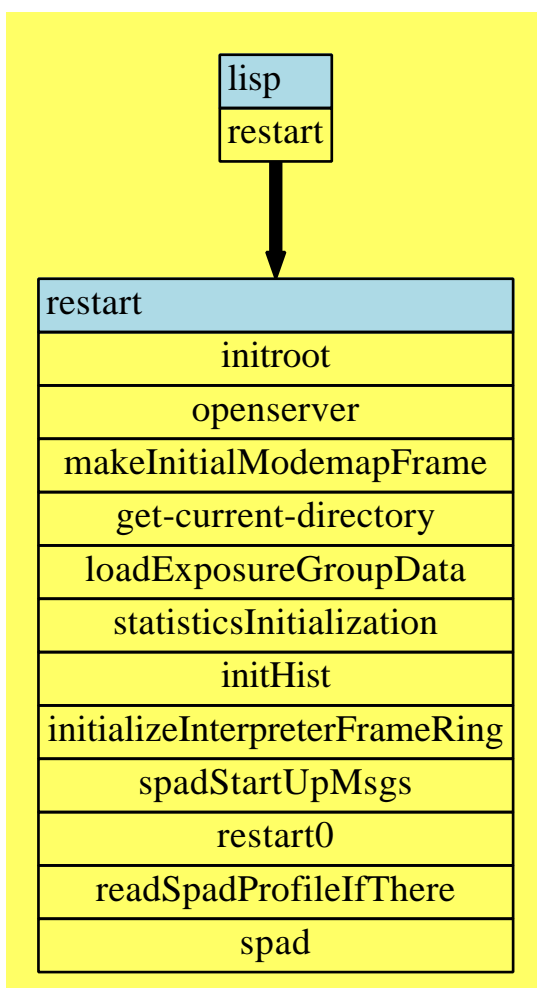

```
(defun set-restart-hook ())
```

```

"Set the restart hook"
#+KCL (setq system::*top-level-hook* 'restart)
#+Lucid (setq boot::restart-hook 'restart)
'restart
)

```

4.3.2 restart function (The restart function)

The restart function is the real root of the world. It sets up memory if we are working in a GCL/akcl version of the system.

The `compiler::*compile-verbose*` flag has been set to nil globally. We do not want to know

about the microsteps of GCL's compile facility.

The `compiler::*suppress-compiler-warnings*` flag has been set to `t`. We do not care that certain generated variables are not used.

The `compiler::*suppress-compiler-notes*` flag has been set to `t`. We do not care that tail recursion occurs.

It sets the current package to be the "BOOT" package which is the standard package in which the interpreter runs.

The "initroot" (5.3.9 p 35) function sets global variables that depend on the AXIOM shell variable. These are needed to find basic files like `s2-us.msgs`, which contains the error message text.

The "openserver" (64.0.23 p 985) function tried to set up the socket connection used for things like hyperdoc. The `$openServerIfTrue` variable starts true, which implies trying to start a server.

The `$IOindex` variable is the number associated with the input prompt. Every successful expression evaluated increments this number until a `)clear all` resets it. Here we set it to the initial value.

Axiom has multiple frames that contain independent information about a computation. There can be several frames at any one time and you can shift back and forth between the frames. By default, the system starts in "frame0" (try the `)frame names` command). See the Frame Mechanism chapter (33.3.1 page 550).

The `$InteractiveFrame` variable contains the state information related to the current frame, which includes things like the last value, the value of all of the variables, etc.

The "printLoadMsgs" (46.29.4 p 733) variable controls whether load messages will be output as library routines are loaded. We disable this by default. It can be changed by using `)set message autoload`.

The "current-directory" (3.1.2 p 7) variable is set to the current directory. This is used by the `)cd` function and some of the compile routines.

The "statisticsInitialization" (?? p ??) function initializes variables used to collect statistics. Currently, only the garbage collector information is initialized.

```
[init-memory-config p34]

                  (|SpadInterpretStream| 1
                    (list 'tim 'daly '? t))))))))))))))

```

5.1.14 defvar \$ncMsgList

— initvars —

```
(defvar |$ncMsgList| nil)
```

5.1.15 defun SpadInterpretStream

The SpadInterpretStream function takes three arguments

str This is passed as an argument to intloopReadConsole

source This is the name of a source file but appears not to be used. It is set to the list (tim daly ?).

interactive? If this is false then various messages are suppressed and input does not use piles. If this is true then the library loading routines might output messages and piles are expected on input (as from a file).

The system commands are handled by the function kept in the “hook” variable `$systemCommandFunction` which has the default function `InterpExecuteSpadSystemCommand`. Thus, when a system command is entered this function is called.

The `$promptMsg` variable is set to the constant S2CTP023. This constant points to a message in `src/doc/messages/s2-us.msgs`. This message does nothing but print the argument value.

5.1.16 defvar \$promptMsg

— initvars —

```
(defvar |$promptMsg| 'S2CTP023)
```

—————

5.1.17 defun GCL cmpnote function

GCL keeps noting the fact that the compiler is performing tail-recursion. Bill Schelter added this as a debugging tool for Axiom and it was never removed. Patching the lisp code in the GCL build fails as the system is actually built from the pre-compiled C code. Thus, we can only step on this message after the fact. The cmpnote function is used nowhere else in GCL so stepping on the function call seems best. We're unhappy with this hack and will try to convince the GCL crowd to fix this.

— defun cmpnote —

```
#+:gcl (defun compiler::cmpnote (&rest x) (declare (ignore x)))

        (|intloopInclude| source 0)))

```

5.2 The Read-Eval-Print Loop

5.2.1 defun intloopReadConsole

Note that this function relies on the fact that lisp can do tail-recursion. The function recursively invokes itself.

The serverReadLine function is a special readline function that handles communication with the session manager code, which is a separate process running in parallel.

We read a line from standard input.

- If it is a null line then we exit Axiom.
- If it is a zero length line we prompt and recurse
- If \$dalymode and open-paren we execute lisp code, prompt and recurse The \$dalymode will interpret any input that begins with an open-paren as a lisp expression rather than Axiom input. This is useful for debugging purposes when most of the input lines will be lisp. Setting \$dalymode non-nil will certainly break user expectations and is to be used with caution.
- If it is “)fi” or “)fin” we drop into lisp. Use the (restart) function to return to the interpreter loop.
- If it starts with “)” we process the command, prompt, and recurse
- If it is a command then we remember the current line, process the command, prompt, and recurse.
- If the input has a trailing underscore (Axiom line-continuation) then we cut off the continuation character and pass the truncated string to ourselves, prompt, and recurse
- otherwise we process the input, prompt, and recurse.

Notice that all but two paths (a null input or a “)fi” or a “)fin”) will end up as a recursive call to ourselves. [top-level p??]

5.3.11 defun Interpret a line of lisp code

This is used to handle)lisp top level commands [nplisp p470]
[\$currentLine p??]

— defun intnplisp —

```
(defun |intnplisp| (s)
  (declare (special |$currentLine|))
  (setq |$currentLine| s)
  (|nplisp| |$currentLine|))
```

5.3.12 Get the current directory

— defun get-current-directory 0 —

```
(defun get-current-directory ()
  "Get the current directory"
  (namestring (truename "")))
```

5.3.13 Prepend the absolute path to a filename

Prefix a filename with the **AXIOM** shell variable. [\$spadroot p12]

— defun make-absolute-filename 0 —

```
(defun make-absolute-filename (name)
  "Prepend the absolute path to a filename"
  (declare (special $spadroot))
  (concatenate 'string $spadroot name))
```

5.3.14 Make the initial modemap frame

```
[copy p??]
[$InitialModemapFrame p9]
```

— defun makeInitialModemapFrame 0 —

```
(defun |makeInitialModemapFrame| ()
  "Make the initial modemap frame"
  (declare (special |$InitialModemapFrame|))
  (copy |$InitialModemapFrame|))
```

5.3.15 defun ncloopEscaped

The ncloopEscaped function will return true if the last non-blank character of a line is an underscore, the Axiom line-continuation character. Otherwise, it returns nil.

— defun ncloopEscaped 0 —

```
(defun |ncloopEscaped| (x)
  (let ((l (length x)))
    (dotimes (i l)
      (when (char= (char x (- l i 1)) #\_) (return t))
      (unless (char= (char x (- l i 1)) #\space) (return nil))))))
```

5.3.16 defun intloopProcessString

```
[setCurrentLine p41]
[intloopProcess p64]
[next p38]
[incString p39]
```

— defun intloopProcessString —

```
(defun |intloopProcessString| (s n)
  (|setCurrentLine| s)
  (|intloopProcess| n t
    (|next| #'|ncloopParse|
      (|next| #'|lineoftoks| (|incString| s)))))
```

5.3.17 defun ncloopParse

[ncloopDQlines p71]
 [npParse p141]
 [dqToList p344]

— defun ncloopParse —

```
(defun |ncloopParse| (s)
  (let (cudr lines stream dq t1)
    (setq t1 (car s))
    (setq dq (car t1))
    (setq stream (cadr t1))
    (setq t1 (|ncloopDQlines| dq stream))
    (setq lines (car t1))
    (setq cudr (cadr t1))
    (cons (list (list lines (|npParse| (|dqToList| dq)))) (cdr s))))
```

5.3.18 defun next

[Delay p103]
 [next1 p38]

— defun next —

```
(defun |next| (f s)
  (|Delay| #'|next1| (list f s)))
```

5.3.19 defun next1

[StreamNull p333]
 [incAppend p87]

[next p38]

— defun next1 —

```
(defun |next1| (&rest z)
  (let (h s f)
    (setq f (car z))
    (setq s (cadr z))
    (cond
      ((|StreamNull| s) |StreamNil|)
      (t
       (setq h (apply f (list s)))
       (|incAppend| (car h) (|next| f (cdr h)))))))
```

—————

5.3.20 defun incString

[incRenumber p74]

[incLude p76]

[Top p77]

— defun incString —

```
(defun |incString| (s)
  (declare (special |Top|))
  (|incRenumber| (|incLude| 0 (list s) 0 (list "strings") (list |Top|))))
```

—————

5.3.21 Call the garbage collector

Call the garbage collector on various platforms.

— defun reclaim 0 —

```
#+abcl
(defun reclaim () "Call the garbage collector" (ext::gc))
#+allegro
(defun reclaim () "Call the garbage collector" (excl::gc t))
#+CCL

#+Lucid
(defun reclaim () "Call the garbage collector" (lcl::gc))
#+sbcl
(defun reclaim () "Call the garbage collector" (sb-ext::gc))

```

5.3.22 defun reroot

The `reroot` function is used to reset the important variables used by the system. In particular, these variables are sensitive to the **AXIOM** shell variable. That variable is renamed internally to be **\$spadroot**. The **reroot** function will change the system to use a new root directory and will have the same effect as changing the **AXIOM** shell variable and rerunning the system from scratch. Note that we have changed from the NAG distribution back to the original form. If you need the NAG version you can push **:tpd** on the ***features*** variable before compiling this file. A correct call looks like:

```

(in-package "BOOT")
(reroot "/spad/mnt/${SYS}")

```

where the `${SYS}` variable is the same one set at build time.

For the example call:

```

(REROOT "/research/test/mnt/ubuntu")

```

the variables are set as:

```

$spadroot = "/research/test/mnt/ubuntu"

$relative-directory-list =
  ("../../../../src/input/"
   "/doc/msgs/"
   "../../../../src/algebra/"
   "../../../../src/interp/"
   "/doc/spadhelp/")

$directory-list =
  ("/research/test/mnt/ubuntu/../../../../src/input/"

```

```

"/research/test/mnt/ubuntu/doc/messages/"
"/research/test/mnt/ubuntu/../../src/algebra/"
"/research/test/mnt/ubuntu/../../src/interp/"
"/research/test/mnt/ubuntu/doc/spadhelp/")

$relative-library-directory-list = ("/algebra/")

$library-directory-list = ("/research/test/mnt/ubuntu/algebra/")

|$defaultMsgDatabaseName| = #p"/research/test/mnt/ubuntu/doc/messages/s2-us.messages"

|$msgDatabaseName| = nil

$current-directory = "/research/test/"

[make-absolute-filename p36]
[$spadroot p12]
[$directory-list p8]
[$relative-directory-list p11]
[$library-directory-list p9]
[$relative-library-directory-list p11]
[$defaultMsgDatabaseName p8]
[$msgDatabaseName p326]
[$current-directory p7]

```

— **defun reroot** —

```

(defun reroot (dir)
  (declare (special $spadroot $directory-list $relative-directory-list
    $library-directory-list $relative-library-directory-list
    |$defaultMsgDatabaseName| |$msgDatabaseName| $current-directory))
  (setq $spadroot dir)
  (setq $directory-list
    (mapcar #'make-absolute-filename $relative-directory-list))
  (setq $library-directory-list
    (mapcar #'make-absolute-filename $relative-library-directory-list))
  (setq |$defaultMsgDatabaseName|
    (pathname (make-absolute-filename "/doc/messages/s2-us.messages")))
  (setq |$msgDatabaseName| ())
  (setq $current-directory $spadroot))

```

5.3.23 defun setCurrentLine

Remember the current line. The cases are:

- If there is no `$currentLine` set it to the input
- Is the current line a string and the input a string? Make them into a list
- Is `$currentLine` not a cons cell? Make it one.
- Is the input a string? Cons it on the end of the list.
- Otherwise stick it on the end of the list

Note I suspect the last two cases do not occur in practice since they result in a dotted pair if the input is not a cons. However, this is what the current code does so I won't change it. `[$currentLine p??]`

— **defun setCurrentLine 0** —

```
(defun |setCurrentLine| (s)
  (declare (special |$currentLine|))
  (cond
    ((null |$currentLine|) (setq |$currentLine| s))
    ((and (stringp |$currentLine|) (stringp s))
     (setq |$currentLine| (list |$currentLine| s)))
    ((not (consp |$currentLine|)) (setq |$currentLine| (cons |$currentLine| s)))
    ((stringp s) (rplacd (last |$currentLine|) (cons s nil))))
  (t (rplacd (last |$currentLine|) s)))
|$currentLine|)
```

—————

5.3.152 defvar \$pfMacros

The \$pfMacros variable is an alist [[id, state, body-pform], ...] where state is one of: mbody, mparam, mlambda

User-defined macros are maintained in a stack of definitions. This is the stack sequence resulting from the command lines:

```
a ==> 3
a ==> 4
```

```

b ==> 7
(
  (|b| |mbody| ((|integer| (|posn| (0 "b ==> 7" 1 1 "strings") . 6)) . "7"))
  (|a| |mbody| ((|integer| (|posn| (0 "a ==> 4" 1 1 "strings") . 6)) . "4"))
  (|a| |mbody| ((|integer| (|posn| (0 "a ==> 3" 1 1 "strings") . 6)) . "3"))
)

```

Chapter 8

Pftrees

8.1 Abstract Syntax Trees Overview

Th functions create and examine abstract syntax trees. These are called pforms, for short.

The pform data structure

- Leaves: [hd, tok, pos] where pos is optional
- Trees: [hd, tree, tree, ...]
- hd is either an id or (id . alist)

The leaves are:

char	:=	('char expr position)
Document	:=	('Document expr position)
error	:=	('error expr position)
expression	:=	('expression expr position)
float	:=	('float expr position)
id	:=	('id expr position)
idsy	:=	('idsy expr position)
integer	:=	('integer expr position)
string	:=	('string expr position)
symbol	:=	('symbol expr position)

The special nodes:

ListOf	:=	('listOf items)
Nothing	:=	('nothing)
SemiColon	:=	('SemiColon (Body: Expr))

The expression nodes:

Add	:= ('Add (Base: [Typed], Addin: Expr))
And	:= ('And left right)
Application	:= ('Application (Op: Expr, Arg: Expr))
Assign	:= ('Assign (LhsItems: [AssLhs], Rhs: Expr))
Attribute	:= ('Attribute (Expr: Primary))
Break	:= ('Break (From: ? Id))
Coerceto	:= ('Coerceto (Expr: Expr, Type: Type))
Collect	:= ('Collect (Body: Expr, Iterators: [Iterator]))
ComDefinition	:= ('ComDefinition (Doc: Document, Def: Definition))
DeclPart	
Definition	:= ('Definition (LhsItems: [Typed], Rhs: Expr))
DefinitionSequence	:= (Args: [DeclPart])
Do	:= ('Do (Body: Expr))
Document	:= ('Document strings)
DWhere	:= ('DWhere (Context: [DeclPart], Expr: [DeclPart]))
EnSequence	:=
Exit	:= ('Exit (Cond: ? Expr, Expr: ? Expr))
Export	:= ('Export (Items: [Typed]))

Special cases of expression nodes are:

- Application. The Op parameter is one of `and`, `or`, `Y`, `|`, `{}`, `[]`, `{|}|`, `[|]|`
- DeclPart. The comment is attached to all signatutres in Typing, Import, Definition, Sequence, DWhere, Macro nodes
- EnSequence. This is either a Tuple or Sequence depending on the argument
- Literal. One of integer symbol expression one zero char string float of the form ('expression expr position)

Chapter 9

Pftree to s-expression translation

Pftree to s-expression translation. Used to interface the new parser technology to the interpreter. The input is a parseTree and the output is an old-parser-style s-expression.

Chapter 10

Keyed Message Handling

Throughout the interpreter there are messages printed using a symbol for a database lookup. This was done to enable translation of these messages languages other than English.

Axiom messages are read from a flat file database and returned as one long string. They are preceded in the database by a key and this is how they are referenced from code. For example, one key is S2IL0001 which means:

S2	Scratchpad II designation
I	from the interpreter
L	originally from LISPLIB BOOT
0001	a sequence number

Each message may contain formatting codes and and parameter codes. The formatting codes are:

%b	turn on bright printing
%ceoff	turn off centering
%ceon	turn on centering
%d	turn off bright printing
%f	user defined printing
%i	start indentation of 3 more spaces
%l	start a new line
%m	math-print an expression
%rjoff	turn off right justification (actually ragged left)
%rjon	turn on right justification (actually ragged left)
%s	pretty-print as an S-expression
%u	unindent 3 spaces
%x#	insert # spaces

The parameter codes look like %1, %2b, %3p, %4m, %5bp, %6s where the digit is the parameter number and the letters following indicate additional formatting. You can indicate as many additional formatting qualifiers as you like, to the degree they make sense.

- The “p” code means to call `prefix2String` on the parameter, a standard way of printing abbreviated types.
- The “P” operator maps `prefix2String` over its arguments.
- The “o” operation formats the argument as an operation name.
- The “b” means to print that parameter in a bold (bright) font.
- The “c” means to center that parameter on a new line.
- The “r” means to right justify (ragged left) the argument.
- The “f” means that the parameter is a list `[fn, :args]` and that “fn” is to be called on “args” to get the text.

Look in the file with the name defined in `$defaultMsgDatabaseName` above for examples.

Chapter 11

Stream Utilities

The input stream is parsed into a large s-expression by repeated calls to Delay. Delay takes a function `f` and an argument `x` and returns a list consisting of `("nonnullstream" f x)`. Eventually multiple calls are made and a large list structure is created that consists of `("nonnullstream" f x ("nonnullstream" f1 x1 ("nonnullstream" f2 x2...`

This delay structure is given to StreamNull which walks along the list looking at the head. If the head is “nonnullstream” then the function is applied to the argument.

So, in effect, the input is “zipped up” into a Delay data structure which is then evaluated by calling StreamNull. This ”zippered stream” parser was a research project at IBM and Axiom was the testbed (which explains the strange parsing technique).

```

Chapter 12

Code Piles

The `insertpile` function converts a line-list to a line-forest where a line is a token-dequeue and has a column which is an integer. An A-forest is an A-tree-list. An A-tree has a root which is an A, and subtrees which is an A-forest.

A forest with more than one tree corresponds to a Scratchpad pile structure $(t_1; t_2; t_3; \dots; t_n)$, and a tree corresponds to a pile item. The `(;` and `)` tokens are inserted into a `l1`-forest, otherwise the root of the first tree is concatenated with its forest. column `t` is the number of spaces before the first non-space in line `t`.

Chapter 15

The Interpreter Syntax

15.1 syntax assignment

— assignment.help —

Immediate, Delayed, and Multiple Assignment

=====

Immediate Assignment

=====

A variable in Axiom refers to a value. A variable has a name beginning with an uppercase or lowercase alphabetic character, "%", or "!". Successive characters (if any) can be any of the above, digits, or "?". Case is distinguished. The following are all examples of valid, distinct variable names:

a	tooBig?	a1B2c3%!?
A	%j	numberOfPoints
beta6	%J	numberofpoints

The "!=" operator is the immediate assignment operator. Use it to associate a value with a variable. The syntax for immediate assignment for a single variable is:

variable := expression

The value returned by an immediate assignment is the value of expression.

a := 1
1

Type: PositiveInteger

The right-hand side of the expression is evaluated, yielding 1. The value is then assigned to a.

```
b := a
1
```

Type: PositiveInteger

The right-hand side of the expression is evaluated, yielding 1. This value is then assigned to b. Thus a and b both have the value 1 after the sequence of assignments.

```
a := 2
2
```

Type: PositiveInteger

What is the value of b if a is assigned the value 2?

```
b
1
```

Type: PositiveInteger

The value of b is left unchanged.

This is what we mean when we say this kind of assignment is immediate. The variable b has no dependency on a after the initial assignment. This is the usual notion of assignment in programming languages such as C, Pascal, and Fortran.

```
=====
Delayed Assignment
=====
```

Axiom provides delayed assignment with "==". This implements a delayed evaluation of the right-hand side and dependency checking. The syntax for delayed assignment is

```
variable == expression
```

The value returned by a delayed assignment is the unique value of Void.

```
a == 1
```

Type: Void

```
b == a
```

Type: Void

Using a and b as above, these are the corresponding delayed assignments.

```

a
  Compiling body of rule a to compute value of type PositiveInteger
  1
    Type: PositiveInteger

```

The right-hand side of each delayed assignment is left unevaluated until the variables on the left-hand sides are evaluated.

```

b
  Compiling body of rule b to compute value of type PositiveInteger
  1
    Type: PositiveInteger

```

This gives the same results as before. But if we change a to 2

```

a == 2
  Compiled code for a has been cleared.
  Compiled code for b has been cleared.
  1 old definition(s) deleted for function or rule a
    Type: Void

```

Then a evaluates to 2, as expected

```

a
  Compiling body of rule a to compute value of type PositiveInteger
  2
    Type: PositiveInteger

```

but the value of b reflects the change to a

```

b
  Compiling body of rule b to compute value of type PositiveInteger
  2
    Type: PositiveInteger

```

Multiple Immediate Assignments

It is possible to set several variables at the same time by using a tuple of variables and a tuple of expressions. A tuple is a collection of things separated by commas, often surrounded by parentheses. The syntax for multiple immediate assignment is

```
( var1, var2, ..., varN ) := ( expr1, expr2, ..., exprN )
```

The value returned by an immediate assignment is the value of exprN.

```
( x, y ) := ( 1, 2 )
2
```

Type: PositiveInteger

This sets *x* to 1 and *y* to 2. Multiple immediate assignments are parallel in the sense that the expressions on the right are all evaluated before any assignments on the left are made. However, the order of evaluation of these expressions is undefined.

```
( x, y ) := ( y, x )
```

1

Type: PositiveInteger

x

2

Type: PositiveInteger

The variable *x* now has the previous value of *y*.

y

1

Type: PositiveInteger

The variable *y* now has the previous value of *x*.

There is no syntactic form for multiple delayed assignments.

15.2 syntax blocks

— blocks.help —

```
=====
Blocks
=====
```

A block is a sequence of expressions evaluated in the order that they appear, except as modified by control expressions such as `leave`, `return`, `iterate`, and `if-then-else` constructions. The value of a block is the value of the expression last evaluated in the block.

To leave a block early, use `"=>"`. For example,

```
i < 0 => x
```

The expression before the `"=>"` must evaluate to true or false. The expression following the `"=>"` is the return value of the block.

A block can be constructed in two ways:

1. the expressions can be separated by semicolons and the resulting expression surrounded by parentheses, and
 2. the expressions can be written on succeeding lines with each line indented the same number of spaces (which must be greater than zero).
- A block entered in this form is called a pile

Only the first form is available if you are entering expressions directly to Axiom. Both forms are available in .input files. The syntax for a simple block of expressions entered interactively is

```
( expression1 ; expression2 ; ... ; expressionN )
```

The value returned by a block is the value of an "=>" expression, or expressionN if no "=>" is encountered.

In .input files, blocks can also be written in piles. The examples given here are assumed to come from .input files.

```
a :=
  i := gcd(234,672)
  i := 2*i**5 - i + 1
  1 / i

      1
-----
23323

Type: Fraction Integer
```

In this example, we assign a rational number to a using a block consisting of three expressions. This block is written as a pile. Each expression in the pile has the same indentation, in this case two spaces to the right of the first line.

```
a := ( i := gcd(234,672); i := 2*i**5 - i + 1; 1 / i )

      1
-----
23323

Type: Fraction Integer
```

Here is the same block written on one line. This is how you are required to enter it at the input prompt.

```
( a := 1; b := 2; c := 3; [a,b,c] )
[1,2,3]

Type: List PositiveInteger
```

AAxiom gives you two ways of writing a block and the preferred way in an .input file is to use a pile. Roughly speaking, a pile is a block whose constituent expressions are indented the same amount. You begin a pile by starting a new line for the first expression, indenting it to the right of the previous line. You then enter the second expression on a new line, vertically aligning it with the first line. And so on. If you need to enter an inner pile, further indent its lines to the right of the outer pile. Axiom knows where a pile ends. It ends when a subsequent line is indented to the left of the pile or the end of the file.

1

15.3 system clef

— clef.help —

Entering printable keys generally inserts new text into the buffer (unless in overwrite mode, see below). Other special keys can be used to modify the text in the buffer. In the description of the keys below, `^n` means Control-n, or holding the CONTROL key down while pressing "n". Errors will ring the terminal bell.

- `^A/^E` : Move cursor to beginning/end of the line.
- `^F/^B` : Move cursor forward/backward one character.
- `^D` : Delete the character under the cursor.
- `^H, DEL` : Delete the character to the left of the cursor.
- `^K` : Kill from the cursor to the end of line.
- `^L` : Redraw current line.
- `^O` : Toggle overwrite/insert mode. Initially in insert mode. Text added in overwrite mode (including yanks) overwrite existing text, while insert mode does not overwrite.
- `^P/^N` : Move to previous/next item on history list.

¹ "if" (15.6 p 395) "repeat" (15.10 p 402) "while" (69.1.2 p 1041) "for" (15.5 p 391) "suchthat" (15.11 p 406) "parallel" (15.9 p 399) "lists" (?? p ??)

`^R/^S` : Perform incremental reverse/forward search for string on the history list. Typing normal characters adds to the current search string and searches for a match. Typing `^R/^S` marks the start of a new search, and moves on to the next match. Typing `^H` or `DEL` deletes the last character from the search string, and searches from the starting location of the last search. Therefore, repeated `DEL`'s appear to unwind to the match nearest the point at which the last `^R` or `^S` was typed. If `DEL` is repeated until the search string is empty the search location begins from the start of the history list. Typing `ESC` or any other editing character accepts the current match and loads it into the buffer, terminating the search.
`^T` : Toggle the characters under and to the left of the cursor.
`^Y` : Yank previously killed text back at current location. Note that this will overwrite or insert, depending on the current mode.
`^U` : Show help (this text).
`TAB` : Perform command completion based on word to the left of the cursor. Words are deemed to contain only the alphanumeric and the `% ! ? _` characters.
`NL, CR` : returns current buffer to the program.

DOS and ANSI terminal arrow key sequences are recognized, and act like:

`up` : same as `^P`
`down` : same as `^N`
`left` : same as `^B`
`right` : same as `^F`

15.4 syntax collection

— collection.help —

```
=====
Collection -- Creating Lists and Streams with Iterators
=====
```

All of the loop expressions which do not use the `repeat` `leave` or `iterate` words can be used to create lists and streams. For example:

This creates a simple list of the integers from 1 to 10:

```
list := [i for i in 1..10]
[1,2,3,4,5,6,7,8,9,10]
Type: List PositiveInteger
```

Create a stream of the integers greater than or equal to 1:

```
stream := [i for i in 1..]
[1,2,3,4,5,6,7,...]
Type: Stream PositiveInteger
```

This is a list of the prime numbers between 1 and 10, inclusive:

```
[i for i in 1..10 | prime? i]
[2,3,5,7]
Type: List PositiveInteger
```

This is a stream of the prime integers greater than or equal to 1:

```
[i for i in 1.. | prime? i]
[2,3,5,7,11,13,17,...]
Type: Stream PositiveInteger
```

This is a list of the integers between 1 and 10, inclusive, whose squares are less than 700:

```
[i for i in 1..10 while i*i < 700]
[1,2,3,4,5,6,7,8,9,10]
Type: List PositiveInteger
```

This is a stream of the integers greater than or equal to 1 whose squares are less than 700:

```
[i for i in 1.. while i*i < 700]
[1,2,3,4,5,6,7,...]
Type: Stream PositiveInteger
```

The general syntax of a collection is

```
[ collectExpression iterator1 iterator2 ... iteratorN ]
```

where each iterator is either a for or a while clause. The loop terminates immediately when the end test of any iterator succeeds or when a return expression is evaluated in collectExpression. The value returned by the collection is either a list or a stream of elements, one for each iteration of the collectExpression.

Be careful when you use while to create a stream. By default Axiom tries to compute and display the first ten elements of a stream. If the while condition is not satisfied quickly, Axiom can spend a long (potentially infinite) time trying to compute the elements. Use

```
)set streams calculate
```

to change the defaults to something else. This also affects the number of terms computed and displayed for power series. For the purposes of these examples we have use this system command to display fewer than ten terms.

15.5 syntax for

— for.help —

```
=====
for loops
=====
```

Axiom provide the for and in keywords in repeat loops, allowing you to integrate across all elements of a list, or to have a variable take on integral values from a lower bound to an upper bound. We shall refer to these modifying clauses of repeat loops as for clauses. These clauses can be present in addition to while clauses (See)help while). As with all other types of repeat loops, leave (see)help leave) can be used to prematurely terminate evaluation of the loop.

The syntax for a simple loop using for is

```
for iterator repeat loopbody
```

The iterator has several forms. Each form has an end test which is evaluated before loopbody is evaluated. A for loop terminates immediately when the end test succeeds (evaluates to true) or when a leave or return expression is evaluated in loopbody. The value returned by the loop is the unique value of Void.

```
=====
for i in n..m repeat
=====
```

If for is followed by a variable name, the in keyword and then an integer segment of the form n..m, the end test for this loop is the predicate $i > m$. The body of the loop is evaluated $m-n+1$ times if this number is greater than 0. If this number is less than or equal to 0, the loop body is not evaluated at all.

The variable i has the value $n, n+1, \dots, m$ for successive iterations of the loop body. The loop variable is a local variable within the loop body. Its value is not available outside the loop body and its value and

type within the loop body completely mask any outer definition of a variable with the same name.

```
for i in 10..12 repeat output(i**3)
1000
1331
1728
```

Type: Void

The loop prints the values of 10^3 , 11^3 , and 12^3 .

```
a := [1,2,3]
[1,2,3]
```

Type: List PositiveInteger

```
for i in 1..#a repeat output(a.i)
1
2
3
```

Type: Void

Iterate across this list using "." to access the elements of a list and the # operation to count its elements.

This type of iteration is applicable to anything that uses ".". You can also use it with functions that use indices to extract elements.

```
m := matrix [ [1,2],[4,3],[9,0] ]
+-      +-
| 1  2 |
| 4  3 |
| 9  0 |
+-      +-

```

Type: Matrix Integer

Define m to be a matrix.

```
for i in 1..nrows(m) repeat output row(m.i)
[1,2]
[4,3]
[9,0]
```

Type: Void

Display the rows of m.

You can iterate with for-loops.

```
for i in 1..5 repeat
  if odd?(i) then iterate
  output(i)
```

```
2
4
```

Type: Void

Display the even integers in a segment.

```
=====
for i in n..m by s repeat
=====
```

By default, the difference between values taken on by a variable in loops such as

```
for i in n..m repeat ...
```

is 1. It is possible to supply another, possibly negative, step value by using the `by` keyword along with `for` and `in`. Like the upper and lower bounds, the step value following the `by` keyword must be an integer. Note that the loop

```
for i in 1..2 by 0 repeat output(i)
```

will not terminate by itself, as the step value does not change the index from its initial value of 1.

```
for i in 1..5 by 2 repeat output(i)
1
3
5
```

Type: Void

This expression displays the odd integers between two bounds.

```
for i in 5..1 by -2 repeat output(i)
5
3
1
```

Type: Void

Use this to display the numbers in reverse order.

```
=====
for i in n.. repeat
=====
```

If the value after the `".."` is omitted, the loop has no end test. A potentially infinite loop is thus created. The variable is given the successive values `n`, `n+1`, `n+2`, ... and the loop is terminated only if a `leave` or `return` expression is evaluated in the loop body. However, you may also add some other modifying clause on the `repeat`, for example,

a while clause, to stop the loop.

```
for i in 15.. while not prime?(i) repeat output(i)
15
16
```

Type: Void

This loop displays the integers greater than or equal to 15 and less than the first prime number greater than 15.

```
=====
for x in l repeat
=====
```

Another variant of the for loop has the form:

```
for x in list repeat loopbody
```

This form is used when you want to iterate directly over the elements of a list. In this form of the for loop, the variable *x* takes on the value of each successive element in *l*. The end test is most simply stated in English: "are there no more *x* in *l*?"

```
l := [0, -5, 3]
[0, -5, 3]
```

Type: List Integer

```
for x in l repeat output(x)
0
-5
3
```

Type: Void

This displays all of the elements of the list *l*, one per line.

Since the list constructing expression

```
expand [n..m]
```

creates the list

```
[n, n+1, ..., m]
```

you might be tempted to think that the loops

```
for i in n..m repeat output(i)
```

and

```
for x in expand [n..m] repeat output(x)
```

are equivalent. The second form first creates the expanded list (no matter how large it might be) and then does the iteration. The first form potentially runs in much less space, as the index variable `i` is simply incremented once per loop and the list is not actually created. Using the first form is much more efficient.

Of course, sometimes you really want to iterate across a specific list. This displays each of the factors of 2400000:

```
for f in factors(factor(2400000)) repeat output(f)
[factor= 2, exponent= 8]
[factor= 3, exponent= 1]
[factor= 5, exponent= 5]
Type: Void
```

15.6 syntax if

— if.help —

```
=====
If-then-else
=====
```

Like many other programming languages, Axiom uses the three keywords `if`, `then`, and `else` to form conditional expressions. The `else` part of the conditional is optional. The expression between the `if` and `then` keywords is a predicate: an expression that evaluates to or is convertible to either true or false, that is, a Boolean.

The syntax for conditional expressions is

```
if predicate then expression1 else expression2
```

where the "else expression2" part is optional. The value returned from a conditional expression is expression1 if the predicate evaluates to true and expression2 otherwise. If no else clause is given, the value is always the unique value of Void.

An if-then-else expression always returns a value. If the else clause is missing then the entire expression returns the unique value of Void. If both clauses are present, the type of the value returned by if is obtained by resolving the types of the values of the two clauses.

The predicate must evaluate to, or be convertible to, an object of type Boolean: true or false. By default, the equal sign "=" creates an equation.

```
x + 1 = y
x + 1 = y
```

Type: Equation Polynomial Integer

This is an equation, not a boolean condition. In particular, it is an object of type Equation Polynomial Integer.

However, for predicates in if expressions, Axiom places a default target type of Boolean on the predicate and equality testing is performed. Thus you need not qualify the "=" in any way. In other contexts you may need to tell Axiom that you want to test for equality rather than create an equation. In these cases, use "@" and a target type of Boolean.

The compound symbol meaning "not equal" in Axiom is "~=". This can be used directly without a package call or a target specification. The expression "a ~= b" is directly translated to "not(a = b)".

Many other functions have return values of type Boolean. These include <, <=, >, >=, ~=, and member?. By convention, operations with names ending in "?" return Boolean values.

The usual rules for files are suspended for conditional expressions. In .input files, the then and else keywords can begin in the same column as the corresponding if by may also appear to the right. Each of the following styles of writing if-then-else expressions is acceptable:

```
if i>0 then output("positive") else output("nonpositive")
```

```
if i>0 then output("positive")
    else output("nonpositive")
```

```
if i>0 then output("positive")
else output("nonpositive")
```

```
if i>0
then output("positive")
else output("nonpositive")
```

```
if i>0
    then output("positive")
    else output("nonpositive")
```

A block can follow the then or else keywords. In the following two assignments to a, the then and else clauses each are followed by two line piles. The value returned in each is the value of the second line.

```
a :=
```

```

if i > 0 then
  j := sin(i * pi())
  exp(j + 1/j)
else
  j := cos(i * 0.5 * pi())
  log(abs(j)**5 + i)

a :=
if i > 0
then
  j := sin(i * pi())
  exp(j + 1/j)
else
  j := cos(i * 0.5 * pi())
  log(abs(j)**5 + i)

```

These are both equivalent to the following:

```

a :=
if i > 0 then (j := sin(i * pi()); exp(j + 1/j))
else (j := cos(i * 0.5 * pi()); log(abs(j)**5 + i))

```

15.7 syntax iterate

— iterate.help —

```

=====
iterate in loops
=====

```

Axiom provides an `iterate` expression that skips over the remainder of a loop body and starts the next loop execution. We first initialize a counter.

```

i := 0
0
                                Type: NonNegativeInteger

```

Display the even integers from 2 to 5:

```

repeat
  i := i + 1
  if i > 5 then leave

```

```

    if odd?(i) then iterate
    output(i)
  2
  4

```

Type: Void

15.8 syntax leave

— leave.help —

```

=====
leave in loops
=====

```

The leave keyword is often more useful in terminating a loop. A leave causes control to transfer to the expression immediately following the loop. As loops always return the unique value of Void, you cannot return a value with leave. That is, leave takes no argument.

```

f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then leave
    i := i + 1
  i

```

Type: Void

This example is a modification of the last example in the previous section. Instead of using return we'll use leave.

```

f()
7

```

Type: PositiveInteger

The loop terminates when factorial(i) gets big enough. The last line of the function evaluates to the corresponding "good" value of i and the function terminates, returning that value.

You can only use leave to terminate the evaluation of one loop. Lets consider a loop within a loop, that is, a loop with a nested loop. First, we initialize two counter variables.

```

(i,j) := (1,1)
1

```

Type: PositiveInteger

```
repeat
  repeat
    if (i + j) > 10 then leave
    j := j + 1
  if (i + j) > 10 then leave
  i := i + 1
```

Type: Void

Nested loops must have multiple leave expressions at the appropriate nesting level. How would you rewrite this so $(i + j) > 10$ is only evaluated once?

```
=====
leave vs => in loop bodies
=====
```

Compare the following two loops:

<pre>i := 1 repeat i := i + 1 i > 3 => i output(i)</pre>	<pre>i := 1 repeat i := i + 1 if i > 3 then leave output(i)</pre>
--	--

In the example on the left, the values 2 and 3 for i are displayed but then the " \Rightarrow " does not allow control to reach the call to output again. The loop will not terminate until you run out of space or interrupt the execution. The variable i will continue to be incremented because the " \Rightarrow " only means to leave the block, not the loop.

In the example on the right, upon reaching 4, the leave will be executed, and both the block and the loop will terminate. This is one of the reasons why both " \Rightarrow " and leave are provided. Using a while clause with the " \Rightarrow " lets you simulate the action of leave.

—

15.9 syntax parallel

— parallel.help —

```
=====
parallel iteration
=====
```

Sometimes you want to iterate across two lists in parallel, or perhaps you want to traverse a list while incrementing a variable.

The general syntax of a repeat loop is

```
iterator1, iterator2, ..., iteratorN repeat loopbody
```

where each iterator is either a for or a while clause. The loop terminates immediately when the end test of any iterator succeeds or when a leave or return expression is evaluated in loopbody. The value returned by the loop is the unique value of Void.

```
l := [1,3,5,7]
    [1,3,5,7]
                                     Type: List PositiveInteger

m := [100,200]
    [100,200]
                                     Type: List PositiveInteger

sum := 0
    0
                                     Type: NonNegativeInteger
```

Here we write a loop to iterate across two lists, computing the sum of the pairwise product of the elements:

```
for x in l for y in m repeat
    sum := sum + x*y
                                     Type: Void
```

The last two elements of `l` are not used in the calculation because `m` has two fewer elements than `l`.

```
sum
700
                                     Type: NonNegativeInteger
```

This is the "dot product".

Next we write a loop to compute the sum of the products of the loop elements with their positions in the loop.

```
l := [2,3,5,7,11,13,17,19,23,29,31,37]
    [2,3,5,7,11,13,17,19,23,29,31,37]
                                     Type: List PositiveInteger

sum := 0
    0
```

Type: NonNegativeInteger

```
for i in 0.. for x in l repeat sum := i * x
Type: Void
```

Here looping stops when the list `l` is exhausted, even though the `for i in 0..` specifies no terminating condition.

```
sum
407
Type: NonNegativeInteger
```

When `"|"` is used to qualify any of the `for` clauses in a parallel iteration, the variables in the predicates can be from an outer scope or from a `for` clause in or to the left of the modified clause.

This is correct:

```
for i in 1..10 repeat
  for j in 200..300 | odd? (i+j) repeat
    output [i,j]
```

But this is not correct. The variable `j` has not been defined outside the inner loop:

```
for i in 1..10 | odd? (i+j) repeat -- wrong, j not defined
  for j in 200..300 repeat
    output [i,j]
```

It is possible to mix several of repeat modifying clauses on a loop:

```
for i in 1..10
  for j in 151..160 | odd? j
    while i + j < 160 repeat
      output [i,j]
[1,151]
[3,153]
Type: Void
```

Here are useful rules for composing loop expressions:

1. while predicates can only refer to variables that are global (or in an outer scope) or that are defined in `for` clauses to the left of the predicate.
2. A "such that" predicate (something following `"|"`) must directly follow a `for` clause and can only refer to variables that are global (or in an outer scope) or defined in the modified `for` clause or any `for` clause to the left.

15.10 syntax repeat

— repeat.help —

```
=====
Repeat Loops
=====
```

A loop is an expression that contains another expression, called the loop body, which is to be evaluated zero or more times. All loops contain the repeat keyword and return the unique value of Void. Loops can contain inner loops to any depth.

The most basic loop is of the form

```
repeat loopbody
```

Unless loopbody contains a leave or return expression, the loop repeats forever. The value returned by the loop is the unique value of Void.

Axiom tries to determine completely the type of every object in a loop and then to translate the loop body to Lisp or even to machine code. This translation is called compilation.

If Axiom decides that it cannot compile the loop, it issues a message stating the problem and then the following message:

```
We will attempt to step through and interpret the code
```

It is still possible that Axiom can evaluate the loop but in interpret-code mode.

```
=====
Return in Loops
=====
```

A return expression is used to exit a function with a particular value. In particular, if a return is in a loop within the function, the loop is terminated whenever the return is evaluated.

```
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
  i := i + 1
```

Type: Void

f()

Type: Void

When factorial(i) is big enough, control passes from inside the loop all the way outside the function, returning the value of i (so we think). What went wrong? Isn't it obvious that this function should return an integer? Well, Axiom makes no attempt to analyze the structure of a loop to determine if it always returns a value because, in general, this is impossible. So Axiom has this simple rule: the type of the function is determined by the type of its body, in this case a block. The normal value of a block is the value of its last expression, in this case, a loop. And the value of every loop is the unique value of Void. So the return type of f is Void.

There are two ways to fix this. The best way is for you to tell Axiom what the return type of f is. You do this by giving f a declaration

f:() -> Integer

prior to calling for its value. This tells Axiom "trust me -- an integer is returned". Another way is to add a dummy expression as follows.

```
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
    i := i + 1
  0
```

Type: Void

Note that the dummy expression will never be evaluated but it is the last expression in the function and will determine the return type.

```
f()
7
```

Type: PositiveInteger

```
=====
leave in loops
=====
```

The leave keyword is often more useful in terminating a loop. A leave causes control to transfer to the expression immediately following the loop. As loops always return the unique value of Void, you cannot return a value with leave. That is, leave takes no argument.

```
f() ==
  i := 1
```

```

repeat
  if factorial(i) > 1000 then leave
  i := i + 1
i

```

Type: Void

This example is a modification of the last example in the previous section. Instead of using return we'll use leave.

```

f()
7

```

Type: PositiveInteger

The loop terminates when factorial(i) gets big enough. The last line of the function evaluates to the corresponding "good" value of i and the function terminates, returning that value.

You can only use leave to terminate the evaluation of one loop. Lets consider a loop within a loop, that is, a loop with a nested loop. First, we initialize two counter variables.

```

(i,j) := (1,1)
1

```

Type: PositiveInteger

```

repeat
  repeat
    if (i + j) > 10 then leave
    j := j + 1
  if (i + j) > 10 then leave
  i := i + 1

```

Type: Void

Nested loops must have multiple leave expressions at the appropriate nesting level. How would you rewrite this so (i + j) > 10 is only evaluated once?

```

=====
leave vs => in loop bodies
=====

```

Compare the following two loops:

<pre> i := 1 repeat i := i + 1 i > 3 => i output(i) </pre>	<pre> i := 1 repeat i := i + 1 if i > 3 then leave output(i) </pre>
--	--

In the example on the left, the values 2 and 3 for i are displayed but

then the "`=>`" does not allow control to reach the call to output again. The loop will not terminate until you run out of space or interrupt the execution. The variable `i` will continue to be incremented because the "`=>`" only means to leave the block, not the loop.

In the example on the right, upon reaching 4, the leave will be executed, and both the block and the loop will terminate. This is one of the reasons why both "`=>`" and `leave` are provided. Using a `while` clause with the "`=>`" lets you simulate the action of `leave`.

```
=====
iterate in loops
=====
```

Axiom provides an `iterate` expression that skips over the remainder of a loop body and starts the next loop execution. We first initialize a counter.

```
i := 0
0
Type: NonNegativeInteger
```

Display the even integers from 2 to 5:

```
repeat
  i := i + 1
  if i > 5 then leave
  if odd?(i) then iterate
  output(i)
2
4
Type: Void
```

Also See:

```
o )help blocks
o )help if
o )help while
o )help for
o )help suchthat
o )help parallel
o )help lists
```

15.11 syntax suchthat

— suchthat.help —

```
=====
Such that predicates
=====
```

A for loop can be followed by a "|" and then a predicate. The predicate qualifies the use of the values from the iterator that follows the for. Think of the vertical bar "|" as the phrase "such that".

```
for n in 0..4 | odd? n repeat output n
1
3
```

Type: Void

This loop expression prints out the integers n in the given segment such that n is odd.

A for loop can also be written

```
for iterator | predicate repeat loopbody
```

which is equivalent to:

```
for iterator repeat if predicate then loopbody else iterate
```

The predicate need not refer only to the variable in the for clause. Any variable in an outer scope can be part of the predicate.

```
for i in 1..50 repeat
  for j in 1..50 | factorial(i+j) < 25 repeat
    output [i,j]
[1,1]
[1,2]
[1,3]
[2,1]
[2,2]
[3,1]
```

Type: Void

15.12 syntax syntax

— syntax.help —

The Axiom Interactive Language has the following features documented here.

More information is available by typing

```
)help feature
```

where feature is one of:

```
assignment -- Immediate and delayed assignments
blocks      -- Blocks of expressions
collection  -- creating lists with iterators
for         -- for loops
if          -- If-then-else statements
iterate     -- using iterate in loops
leave       -- using leave in loops
parallel    -- parallel iterations
repeat      -- repeat loops
suchthat    -- suchthat predicates
while       -- while loops
```

—

15.13 syntax while

— while.help —

```
=====
while loops
=====
```

The repeat in a loop can be modified by adding one or more while clauses. Each clause contains a predicate immediately following the while keyword. The predicate is tested before the evaluation of the body of the loop. The loop body is evaluated whenever the predicate in a while clause is true.

The syntax for a simple loop using while is

```
while predicate repeat loopbody
```

The predicate is evaluated before loopbody is evaluated. A while loop terminates immediately when predicate evaluates to false or when a leave or return expression is evaluated. See `)help repeat` for more information on leave and return.

Here is a simple example of using while in a loop. We first initialize the counter.

```
i := 1
1
                                     Type: PositiveInteger

while i < 1 repeat
  output "hello"
  i := i + 1
                                     Type: Void
```

The steps involved in computing this example are

- (1) set i to 1
- (2) test the condition `i < 1` and determine that it is not true
- (3) do not evaluate the loop body and therefore do not display "hello"

```
(x, y) := (1, 1)
1
                                     Type: PositiveInteger
```

If you have multiple predicates to be tested use the logical and operation to separate them. Axiom evaluates these predicates from left to right.

```
while x < 4 and y < 10 repeat
  output [x,y]
  x := x + 1
  y := y + 2
[1,1]
[2,3]
[3,5]
                                     Type: Void
```

A leave expression can be included in a loop body to terminate a loop even if the predicate in any while clauses are not false.

```
(x, y) := (1, 1)
1
                                     Type: PositiveInteger
```

```
while x < 4 and y < 10 repeat
  if x + y > 7 then leave
```

```
output [x,y]
x := x + 1
y := y + 2
[1,1]
[2,3]
```

Type: Void

Chapter 16

Abstract Syntax Trees (ptrees)

Abstract Syntax Trees

These functions create and examine abstract syntax trees. These are called pform, for short.

!! This file also contains constructors for concrete syntax, although
!! they should be somewhere else.

THE PFORM DATA STRUCTURE

Leaves: [hd, tok, pos]

Trees: [hd, tree, tree, ...]

hd is either an id or (id . alist)

Chapter 18

Function Selection

New Selection of Modemaps

selection of applicable modemaps is done in two steps:

first it tries to find a modemap inside an argument domain, and if this fails, by evaluation of pattern modemaps the result is a list of functions with signatures, which have the following form:

[sig,elt,cond] where

sig is the signature gained by evaluating the modemap condition

elt is the slot number to get the implementation

cond are runtime checks which are the results of evaluating the modemap condition

the following flags are used:

\$Coerce is NIL, if function selection is done which requires exact matches (e.g. for coercion functions)

if \$SubDom is true, then runtime checks have to be compiled

18.0.15 defun ofCategory

[identp p1048]

[ofCategory p419]

[hasCaty p420]

[\$Subst p??]

[\$hope p??]

— defun ofCategory —

```
(defun |ofCategory| (dom cat)
  (let (|$Subst| |$hope|)
    (declare (special |$Subst| |$hope|))

Chapter 19

System Command Handling

The system commands are the top-level commands available in Axiom that can all be invoked by prefixing the symbol with a closed-paren. Thus, to see they copyright you type:

```
)copyright
```

New commands need to be added to this table. The command invoked will be the first entry of the pair and the “user level” of the command will be the second entry.

See:

- The “abbreviations” (20.2.1 p 481) command
- The “boot” (5.1.8 p 25) command
- The “browse” (?? p ??) command
- The “cd” (?? p ??) command
- The “clear” (24.3.1 p 497) command
- The “close” (25.2.2 p 508) command
- The “compile” (?? p ??) command
- The “copyright” (27.2.1 p 520) command
- The “credits” (28.3.1 p 523) command

(|zsystemdevelopment|    . |interpreter|)
)))

```

19.1.2 defvar \$syscommands

This table is used to look up a symbol to see if it might be a command.

— **initvars** —

```
(defvar $syscommands nil)
```

— **postvars** —

```

(eval-when (eval load)
  (setq $syscommands (mapcar #'car |$systemCommands|)))

```

19.1.3 defvar \$noParseCommands

This is a list of the commands which have their arguments passed verbatim. Certain functions, such as the lisp function need to be able to handle all kinds of input that will not be acceptable to the interpreter.

— **initvars** —

```
(defvar |$noParseCommands| nil)
```

— **postvars** —

```
(eval-when (eval load)
  (setq |$noParseCommands|
    '(|boot| |copyright| |credits| |fin| |lisp| |pquit| |quit|
      |synonym| |system| |trademark| )))
```

19.2 Functions

19.2.1 defun handleNoParseCommands

The system commands given by the global variable `$noParseCommands` require essentially no preprocessing/parsing of their arguments. Here we dispatch the functions which implement these commands.

There are four standard commands which receive arguments

- boot
- lisp
- synonym
- system

There are six standard commands which do not receive arguments –

- quit
- fin
- pquit
- credits
- copyright
- trademark

As these commands do not necessarily exhaust those mentioned in `$noParseCommands`, we provide a generic dispatch based on two conventions: commands which do not require an argument name themselves, those which do have their names prefixed by “np”. This makes it possible to dynamically define new system commands provided you handle the argument parsing.

19.2.2 defun Handle a top level command

-)abbreviation remove nameOrAbbrev

Command Description:

This command is used to query, set and remove abbreviations for category, domain and package constructors. Every constructor must have a unique abbreviation. This abbreviation is part of the name of the subdirectory under which the components of the compiled constructor are stored. Furthermore, by issuing this command you let the system know what file to load automatically if you use a new constructor. Abbreviations must start with a letter and then be followed by up to seven letters or digits. Any letters appearing in the abbreviation must be in uppercase.

When used with the query argument, this command may be used to list the name associated with a particular abbreviation or the abbreviation for a constructor. If no abbreviation or name is given, the names and corresponding abbreviations for all constructors are listed.

The following shows the abbreviation for the constructor List:

```
)abbreviation query List
```

The following shows the constructor name corresponding to the abbreviation NNI:

```
)abbreviation query NNI
```

The following lists all constructor names and their abbreviations.

```
)abbreviation query
```

To add an abbreviation for a constructor, use this command with category, domain or package. The following add abbreviations to the system for a category, domain and package, respectively:

```
)abbreviation domain SET Set
)abbreviation category COMPCAT ComplexCategory
)abbreviation package LIST2MAP ListToMap
```

If the)quiet option is used, no output is displayed from this command. You would normally only define an abbreviation in a library source file. If this command is issued for a constructor that has already been loaded, the constructor will be reloaded next time it is referenced. In particular, you can use this command to force the automatic reloading of constructors.

To remove an abbreviation, the remove argument is used. This is usually only used to correct a previous command that set an abbreviation for a constructor name. If, in fact, the abbreviation does exist, you are prompted for confirmation of the removal request. Either of the following commands will remove the abbreviation VECTOR2 and the constructor name VectorFunctions2 from the system:

```
)abbreviation remove VECTOR2
)abbreviation remove VectorFunctions2
```

)boot help page Command

21.1 boot help page man page

— boot.help —

```
=====
A.3. )boot
=====
```

User Level Required: development

Command Syntax:

-)boot bootExpression

Command Description:

This command is used by AXIOM system developers to execute expressions written in the BOOT language. For example,

```
)boot times3(x) == 3*x
```

creates and compiles the Lisp function ‘‘times3’’ obtained by translating the BOOT code.

Also See:

- o)fin
- o)lisp
- o)set
- o)system

1

21.2 Functions

This command is in the list of `$noParseCommands` 19.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 19.2.1

¹ “fin” (32.1.1 p 546) “lisp” (?? p ??) “set” (46.36.1 p 805) “system” (?? p ??)

Chapter 22

)browse help page Command

22.1 browse help page man page

— browse.help —

User Level Required: development

Command Syntax:

```
)browse
```

Command Description:

This command is used by Axiom system users to start the Axiom top level loop listening for browser connections.

—————

22.2 Overview

The Axiom book on the help browser is a complete rewrite of the hyperdoc mechanism. There are several components that were needed to make this function. Most of the web browser components are described in bookvol11.pamphlet. This portion describes some of the design issues needed to support the interface.

The axServer command takes a port (defaulting to 8085) and a program to handle the browser interaction (defaulting to multiServ). The axServer function opens the port, constructs the

stream, and passes the stream to multiServ. The multiServ loop processes one interaction at a time.

So the basic process is that the Axiom “)browse” command opens a socket and listens for http requests. Based on the type of request (either ‘GET’ or ‘POST’) and the content of the request, which is one of:

- command - algebra request/response
- lispcall - a lisp s-expression to be evaluated
- showcall - an Axiom)show command

the multiServ function will call a handler function to evaluate the command line and construct a response. GET requests result in a new browser page. POST requests result in an inline result.

Most responses contain the fields:

- stepnum - this is the Axiom step number
- command - this is the original command from the browser
- algebra - this is the Axiom 2D algebra output
- mathml - this is the MathML version of the Axiom algebra
- type - this is the type of the Axiom result

22.3 Browsers, MathML, and Fonts

This work has the Firefox browser as its target. Firefox has built-in support for MathML, javascript, and XMLHttpRequest handling. More details are available in bookvol11.pamphlet but the very basic machinery for communication with the browser involves a dance between the browser and the multiServ function (see the axserver.spad.pamphlet).

In particular, a simple request is embedded in a web page as:

```
<ul>
<li>
  <input type="submit" id="p3" class="subbut"
    onclick="makeRequest('p3');"
    value="sin(x)" />
  <div id="ansp3"><div></div></div>
</li>
</ul>
```

which says that this is an html “input” field of type “submit”. The CSS display class is “subbut” which is of a different color than the surrounding text to make it obvious that you can click on this field. Clickable fields that have no response text are of class “noresult”.

The javascript call to “makeRequest” gives the “id” of this input field, which must be unique in the page, as an argument. In this case, the argument is ‘p3’. The “value” field holds the display text which will be passed back to Axiom as a command.

When the result arrives the “showanswer” function will select out the mathml field of the response, construct the “id” of the html div to hold the response by concatenating the string “ans” (answer) to the “id” of the request resulting, in this case, as “ansp3”. The “showanswer” function will find this div and replace it with a div containing the mathml result.

The “makeRequest” function is:

```
function makeRequest(arg) {
  http_request = new XMLHttpRequest();
  var command = cmdline(arg);
  //alert(command);
  http_request.open('POST', '127.0.0.1:8085', true);
  http_request.onreadystatechange = handleResponse;
  http_request.setRequestHeader('Content-Type', 'text/plain');
  http_request.send("command="+command);
  return(false);
}
```

It contains a request to open a local server connection to Axiom, sets “handleResponse” as the function to call on reply, sets up the type of request, fills in the command field, and sends off the http request.

When a response is received, the “handleResponse” function checks for the correct reply state, strips out the important text, and calls “showanswer”.

```
function handleResponse() {
  if (http_request.readyState == 4) {
    if (http_request.status == 200) {
      showanswer(http_request.responseText,'mathAns');
    } else
    {
      alert('There was a problem with the request.'+ http_request.statusText);
    }
  }
}
```

See bookvol11.pamphlet for further details.

22.4 The axServer/multiServ loop

The basic call to start an Axiom browser listener is:

```
)set message autoload off
)set output mathml on
axServer(8085,multiServ)$AXSERV
```

This call sets the port, opens a socket, attaches it to a stream, and then calls “multiServ” with that stream. The “multiServ” function loops serving web responses to that port.

22.5 The)browse command

In order to make the whole process cleaner the function “)browse” handles the details. This code creates the command-line function for)browse

The browse function does the internal equivalent of the following 3 command line statments:

```
)set message autoload off
)set output mathml on
axServer(8085,multiServ)$AXSERV
```

which causes Axiom to start serving web pages on port 8085

For those unfamiliar with calling algebra from lisp there are a few points to mention.

The loadLib needs to be called to load the algebra code into the image. Normally this is automatic but we are not using the interpreter so we need to do this “by hand”.

Each algebra file contains a “constructor function” which builds the domain, which is a vector, and then caches the vector so that every call to the contructor returns an EQ vector, that is, the same vector. In this case, we call the constructor |AxiomServer|

The axServer function was mangled internally to |AXSERV;axServer;IMV;2|. The multiServ function was mangled to |AXSERV;multiServ;SeV;3| Note well that if you change axserver.spad these names might change which will generate the error message along the lines of:

```
System error:
The function $\vert$AXSERV;axServer;IMV;2$\vert$ is undefined.
```

To fix this you need to look at int/algebra/AXSERV.nrlib/code.lsp and find the new mangled function name. A better solution would be to dynamically look up the surface names in the domain vector.

Each Axiom function expects the domain vector as the last argument. This is not obvious from the call as the interpreter supplies it. We must do that “by hand”.

We don’t call the multiServ function. We pass it as a parameter to the axServer function. When it does get called by the SPADCALL macro it needs to be a lisp pair whose car is the function and whose cdr is the domain vector. We construct that pair here as the second argument to axServer. The third, hidden, argument to axServer is the domain vector which we supply “by hand”.

The socket can be supplied on the command line but defaults to 8085. Axiom supplies the arguments as a list.

22.6 Variables Used

22.7 Functions

```
[set p805]
[loadLib p1037]
[AxiomServer p??]
[AXSERV;axServer;IMV;2 p??]
```

— defun browse —

```
(defun |browse| (socket)
  (let (axserv browser)
    (if socket
      (setq socket (car socket))
      (setq socket 8085))
    (|set| '(|mes| |auto| |off|))
    (|set| '(|out| |mathml| |on|))
    (|loadLib| '|AxiomServer|)
    (setq axserv (|AxiomServer|))
    (setq browser
      (|AXSERV;axServer;IMV;2| socket
        (cons #'|AXSERV;multiServ;SeV;3| axserv) axserv))))
```

Now we have to bolt it into Axiom. This involves two lookups.

We create the lisp pair

```
(|browse| . |development|)
```

and cons it into the \$systemCommands command table. This allows the command to be executed in development mode. This lookup decides if this command is allowed. It also has the side-effect of putting the command into the \$SYSCOMMANDS variable which is used to determine if the token is a command.

22.8 The server support code

Chapter 23

)cd help page Command

23.1 cd help page man page

— cd.help —

```
=====
A.4. )cd
=====
```

User Level Required: interpreter

Command Syntax:

-)cd directory

Command Description:

This command sets the AXIOM working current directory. The current directory is used for looking for input files (for)read), AXIOM library source files (for)compile), saved history environment files (for)history)restore), compiled AXIOM library files (for)library), and files to edit (for)edit). It is also used for writing spool files (via)spool), writing history input files (via)history)write) and history environment files (via)history)save),and compiled AXIOM library files (via)compile).

If issued with no argument, this command sets the AXIOM current directory to your home directory. If an argument is used, it must be a valid directory name. Except for the ‘)’ at the beginning of the command, this has the same syntax as the operating system cd command.

Also See:

o)compile

- o `)edit`
- o `)history`
- o `)library`
- o `)read`
- o `)spool`

Chapter 24

)clear help page Command

24.1 clear help page man page

— clear.help —

```
=====
A.6. )clear
=====
```

User Level Required: interpreter

Command Syntax:

```
- )clear all
- )clear completely
- )clear properties all
- )clear properties obj1 [obj2 ...]
- )clear value      all
- )clear value      obj1 [obj2 ...]
- )clear mode       all
- )clear mode       obj1 [obj2 ...]
```

Command Description:

This command is used to remove function and variable declarations, definitions and values from the workspace. To empty the entire workspace and reset the step counter to 1, issue

```
)clear all
```

To remove everything in the workspace but not reset the step counter, issue

```
)clear properties all
```

To remove everything about the object `x`, issue

```
)clear properties x
```

To remove everything about the objects `x`, `y` and `f`, issue

```
)clear properties x y f
```

The word `properties` may be abbreviated to the single letter `'p'`.

```
)clear p all
```

```
)clear p x
```

```
)clear p x y f
```

All definitions of functions and values of variables may be removed by either

```
)clear value all
```

```
)clear v all
```

This retains whatever declarations the objects had. To remove definitions and values for the specific objects `x`, `y` and `f`, issue

```
)clear value x y f
```

```
)clear v x y f
```

To remove the declarations of everything while leaving the definitions and values, issue

```
)clear mode all
```

```
)clear m all
```

To remove declarations for the specific objects `x`, `y` and `f`, issue

```
)clear mode x y f
```

```
)clear m x y f
```

The `)display names` and `)display properties` commands may be used to see what is currently in the workspace.

The command

```
)clear completely
```

does everything that `)clear all` does, and also clears the internal system function and constructor caches.

Also See:

- o `)display`

```
o )history
o )undo
```

)close help page Command

25.1 close help page man page

— close.help —

```
=====
A.5. )close
=====
```

User Level Required: interpreter

Command Syntax:

-)close
-)close)quietly

Command Description:

This command is used to close down interpreter client processes. Such processes are started by HyperDoc to run AXIOM examples when you click on their text. When you have finished examining or modifying the example and you do not want the extra window around anymore, issue

)close

to the AXIOM prompt in the window.

If you try to close down the last remaining interpreter client process, AXIOM will offer to close down the entire AXIOM session and return you to the operating system by displaying something like

This is the last AXIOM session. Do you want to kill AXIOM?

Type "y" (followed by the Return key) if this is what you had in mind. Type "n" (followed by the Return key) to cancel the command.

You can use the)quietly option to force AXIOM to close down the interpreter client process without closing down the entire AXIOM session.

Also See:

- o)quit
- o)pquit

```

Chapter 26

)compile help page Command

26.1 compile help page man page

— compile.help —

```
=====
A.7. )compile
=====
```

User Level Required: compiler

Command Syntax:

-)compile
-)compile fileName
-)compile fileName.spad
-)compile directory/fileName.spad
-)compile fileName)quiet
-)compile fileName)noquiet
-)compile fileName)break
-)compile fileName)nobreak
-)compile fileName)library
-)compile fileName)nolibrary
-)compile fileName)vartrace
-)compile fileName)constructor nameOrAbbrev

Command Description:

You use this command to invoke the AXIOM library compiler. This compiles files with file extension .spad with the AXIOM system compiler. The command first looks in the standard system directories for files with extension .spad.

Should you not want the `)library` command automatically invoked, call `)compile` with the `)nolibrary` option. For example,

```
)compile mycode )nolibrary
```

By default, the `)library` system command exposes all domains and categories it processes. This means that the AXIOM interpreter will consider those domains and categories when it is trying to resolve a reference to a function. Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `)library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `)nolibrary` option on `)compile` and the `)noexpose` option in the `)library` command. For example,

```
)compile mycode.spad )nolibrary
)library mycode )noexpose
```

Once you have established your own collection of compiled code, you may find it handy to use the `)dir` option on the `)library` command. This causes `)library` to process all compiled code in the specified directory. For example,

```
)library )dir /u/jones/as/quantum
```

You must give an explicit directory after `)dir`, even if you want all compiled code in the current working directory processed.

```
)library )dir .
```

You can compile category, domain, and package constructors contained in files with file extension `.spad`. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file `matrix.spad`. If you do not specify a directory, the working current directory (see description of command `)cd`) is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined. The list of

`commands` serves as a table of contents for the file.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the `.NRLIB` file extension. For example, the directory containing the compiled code for the `MATRIX` constructor is called `MATRIX.NRLIB`. The `)nolibrary` option says that such files should not be created.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. (see description of command `)trace`). Without this option, this code is suppressed and one cannot use the `)vars` option for the `trace` command.

The `)constructor` option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows `)constructor`. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the `RectangularMatrix` constructor defined in `matrix.spad`.

The `)break` and `)nobreak` options determine what the compiler does when it encounters an error. `)break` is the default and it indicates that processing should stop at the first error. The value of the `)set break` variable then controls what happens.

Also See:

- o `)abbreviation`
- o `)edit`
- o `)library`

```
(defun |describe| (l)
  (describeSpad2Cmd l))
```

29.2.2 defun describeSpad2Cmd

The describe command prints cleaned-up comment strings from the algebra libraries. It can print strings associated with a category, domain, package, or by operation.

This implements command line options of the form:

```
)describe categoryName [internal]
)describe domainName   [internal]
)describe packageName   [internal]
```

The describeInternal function will either call the “dc” function to describe the internal representation of the argument or it will print a cleaned up version of the text for the

"Description" keyword in the Category, Domain, or Package source code. [selectOptionLC p477]

Chapter 30

)display help page Command

30.1 display help page man page

— display.help —

```
=====
A.8. )display
=====
```

User Level Required: interpreter

Command Syntax:

-)display all
-)display properties
-)display properties all
-)display properties [obj1 [obj2 ...]]
-)display value all
-)display value [obj1 [obj2 ...]]
-)display mode all
-)display mode [obj1 [obj2 ...]]
-)display names
-)display operations opName

Command Description:

This command is used to display the contents of the workspace and signatures of functions with a given name. (A signature gives the argument and return types of a function.)

The command

`)display names`

lists the names of all user-defined objects in the workspace. This is useful if you do not wish to see everything about the objects and need only be reminded of their names.

The commands

```
)display all
)display properties
)display properties all
```

all do the same thing: show the values and types and declared modes of all variables in the workspace. If you have defined functions, their signatures and definitions will also be displayed.

To show all information about a particular variable or user functions, for example, something named `d`, issue

```
)display properties d
```

To just show the value (and the type) of `d`, issue

```
)display value d
```

To just show the declared mode of `d`, issue

```
)display mode d
```

All modemaps for a given operation may be displayed by using `)display` operations. A modemap is a collection of information about a particular reference to an operation. This includes the types of the arguments and the return value, the location of the implementation and any conditions on the types. The modemap may contain patterns. The following displays the modemaps for the operation `FromcomplexComplexCategory`:

```
)d op complex
```

Also See:

- o `)clear`
- o `)history`
- o `)set`
- o `)show`
- o `)what`

30.1.1 defvar \$displayOptions

The current value of \$displayOptions is

— **initvars** —

```
(defvar |$displayOptions|
  '(|abbreviations| |all| |macros| |modes| |names| |operations|
    |properties| |types| |values|))
```

—————

30.2 Functions

30.2.1 defun display

This trivial function satisfies the standard pattern of making a user command match the name of the function which implements the command. That command immediatly invokes a “Spad2Cmd” version. [displaySpad2cmd p??]

— **defun display** —

```
(defun |display| (l)
  (displaySpad2Cmd l))
```

—————

30.2.2 displaySpad2Cmd

We process the options to the command and call the appropriate display function. There are really only 4 display functions. All of the other options are just subcases.

There is a slight mismatch between the \$displayOptions list of symbols and the options this command accepts so we have a cond branch to clean up the option variable. This allows for the options to be plural.

If we fall all the way thru we use the \$displayOptions list to construct a list of strings for the sayMessage function and tell the user what options are available. [abbQuery p534]

```
[opOf p??]
[listConstructorAbbreviations p482]
[displayOperations p535]
[displayMacros p536]
[displayWorkspaceNames p452]

      (t
        (|sayKeyedMsg| 's2iz0003 (list x))))))
```

30.2.4 defun `displayOperations`

This function takes a list of operation names. If the list is null we query the user to see if they want all operations printed. Otherwise we print the information for the requested symbols. [reportOpSymbol p??]

[yesanswer p535]
[sayKeyedMsg p329]

— defun `displayOperations` —

```
(defun |displayOperations| (l)
  (if l
    (dolist (op l) (|reportOpSymbol| op))
    (if (yesanswer)
      (dolist (op (|allOperations|)) (|reportOpSymbol| op))
      (|sayKeyedMsg| 's2iz0059 nil))))
```

30.2.5 defun `yesanswer`

This is a trivial function to simplify the logic of `displaySpad2Cmd`. If the user didn't supply an argument to the `)display op` command we ask if they wish to have all information about all Axiom operations displayed. If the answer is either Y or YES we return true else nil.

         (|displayMacro| macro))))
      ((|member| macro pmacs) '|iterate|))))
   nil))))

```

30.2.7 defun sayExample

This function expects 2 arguments, the documentation string and the name of the operation. It searches the documentation string for ++X lines. These lines are examples lines for functions. They look like ordinary ++ comments and fit into the ordinary comment blocks. So, for example, in the plot.spad.pamphlet file we find the following function signature:

```

plot: (F -> F,R) -> %
++ plot(f,a..b) plots the function \spad{f(x)}
++ on the interval \spad{[a,b]}.
++
++X fp:=(t:DFLOAT):DFLOAT +-> sin(t)
++X plot(fp,-1.0..1.0)$PLOT

```

This function splits out and prints the lines that begin with ++X.

A minor complication of printing the examples is that the lines have been processed into internal compiler format. Thus the lines that read:

```

++X fp:=(t:DFLOAT):DFLOAT +-> sin(t)
++X plot(fp,-1.0..1.0)$PLOT

```

are actually stored as one long line containing the example lines

```

"\indented{1}{plot(\spad{f},{a}..\spad{b}) plots the function

```

```

\\spad{f(x)} \\indented{1}{on the interval \\spad{[a,{b}]}.
```

\\blankline

```

\\spad{X} fp:=(t:DFLOAT):DFLOAT +-> sin(\\spad{t})
\\spad{X} plot(\\spad{fp},{}\\spad{-1}.0..1.0)\\$PLOT"
```

So when we have an example line starting with ++X, it gets converted to the compiler to \\spad{X}. So each example line is delimited by \\spad{X}.

The compiler also removes the newlines so if there is a subsequent \\spad{X} in the docstring then it implies multiple example lines and we loop over them, splitting them up at the delimiter.

If there is only one then we clean it up and print it. [cleanupLine p??]
[sayNewLine p??]

— defun sayExample —

```

(defun sayExample (docstring)
  (let (line point)
    (when (setq point (search "spad{X}" docstring))
      (setq line (subseq docstring (+ point 8)))
      (do ((mark (search "spad{X}" line) (search "spad{X}" line)))
          ((null mark))
        (princ (cleanupLine (subseq line 0 mark)))
        (|sayNewLine|)
        (setq line (subseq line (+ mark 8))))
      (princ (cleanupLine line))
      (|sayNewLine|)
      (|sayNewLine|))))
```

—————

30.2.8 defun cleanupLine

This function expects example lines in internal format that has been partially processed to remove the prefix. Thus we get lines that look like:

```

fp:=(t:DFLOAT):DFLOAT +-> sin(\\spad{t})
plot(\\spad{fp},{}\\spad{-1}.0..1.0)\\$PLOT
```

It removes all instances of {}, and \, and unwraps the spad{} call, leaving only the argument. We return lines that look like:

```

fp:=(t:DFLOAT):DFLOAT +-> sin(t)
plot(fp,-1.0..1.0)$PLOT
```

which is hopefully exactly what the user wrote.

The compiler inserts {} as a space so we remove it. We remove all of the \ characters. We remove all of the `spad{...}` delimiters which will occur around other `spad` variables. Technically we should search recursively for the matching delimiter rather than the next brace but the problem does not arise in practice.

— **defun cleanupLine 0** —

```
(defun cleanupLine (line)
  (do ((mark (search "{}" line) (search "{}" line)))
      ((null mark))
      (setq line
        (concatenate 'string (subseq line 0 mark) (subseq line (+ mark 2))))))
  (do ((mark (search "\\" line) (search "\\" line)))
      ((null mark))
      (setq line
        (concatenate 'string (subseq line 0 mark) (subseq line (+ mark 1))))))
  (do ((mark (search "spad{" line) (search "spad{" line)))
      ((null mark))
      (let (left point mid right)
        (setq left (subseq line 0 mark))
        (setq point (search "}" line :start2 mark))
        (setq mid (subseq line (+ mark 5) point))
        (setq right (subseq line (+ point 1)))
        (setq line (concatenate 'string left mid right))))
    line)
```

Chapter 31

)edit help page Command

31.1 edit help page man page

— edit.help —

```
=====
A.9. )edit
=====
```

User Level Required: interpreter

Command Syntax:

```
- )edit [filename]
```

Command Description:

This command is used to edit files. It works in conjunction with the `)read` and `)compile` commands to remember the name of the file on which you are working. By specifying the name fully, you can edit any file you wish. Thus

```
)edit /u/julius/matrix.input
```

will place you in an editor looking at the file `/u/julius/matrix.input`. By default, the editor is `vi`, but if you have an `EDITOR` shell environment variable defined, that editor will be used. When AXIOM is running under the X Window System, it will try to open a separate `xterm` running your editor if it thinks one is necessary. For example, under the Korn shell, if you issue

```
export EDITOR=emacs
```

then the `emacs` editor will be used by `)edit`.

If you do not specify a file name, the last file you edited, read or compiled will be used. If there is no ‘‘last file’’ you will be placed in the editor editing an empty unnamed file.

It is possible to use the)system command to edit a file directly. For example,

```
)system emacs /etc/rc.tcpip

calls emacs to edit the file.
```

Also See:

- o)system
- o)compile
- o)read

32.2 Functions

This command is in the list of `$noParseCommands` 19.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 19.2.1

Chapter 33

)frame help page Command

33.1 frame help page man page

— frame.help —

```
=====
A.11. )frame
=====
```

User Level Required: interpreter

Command Syntax:

-)frame new frameName
-)frame drop [frameName]
-)frame next
-)frame last
-)frame names
-)frame import frameName [objectName1 [objectName2 ...]]
-)set message frame on | off
-)set message prompt frame

Command Description:

A frame can be thought of as a logical session within the physical session that you get when you start the system. You can have as many frames as you want, within the limits of your computer's storage, paging space, and so on. Each frame has its own step number, environment and history. You can have a variable named a in one frame and it will have nothing to do with anything that might be called a in any other frame.

Some frames are created by the HyperDoc program and these can have pretty

strange names, since they are generated automatically. To find out the names of all frames, issue

```
)frame names
```

It will indicate the name of the current frame.

You create a new frame ‘‘quark’’ by issuing

```
)frame new quark
```

The history facility can be turned on by issuing either `)set history on` or `)history on`. If the history facility is on and you are saving history information in a file rather than in the AXIOM environment then a history file with filename `quark.ahx` will be created as you enter commands. If you wish to go back to what you were doing in the ‘‘initial’’ frame, use

```
)frame next
```

or

```
)frame last
```

to cycle through the ring of available frames to get back to ‘‘initial’’.

If you want to throw away a frame (say ‘‘quark’’), issue

```
)frame drop quark
```

If you omit the name, the current frame is dropped.

If you do use frames with the history facility on and writing to a file, you may want to delete some of the older history files. These are directories, so you may want to issue a command like `rm -r quark.ahx` to the operating system.

You can bring things from another frame by using `)frame import`. For example, to bring the `f` and `g` from the frame ‘‘quark’’ to the current frame, issue

```
)frame import quark f g
```

If you want everything from the frame ‘‘quark’’, issue

```
)frame import quark
```

You will be asked to verify that you really want everything.

There are two `)set` flags to make it easier to tell where you are.

```
)set message frame on | off
```

will print more messages about frames when it is set on. By default, it is off.

```
)set message prompt frame
```

will give a prompt that looks like

```
initial (1) ->
```

when you start up. In this case, the frame name and step make up the prompt.

Also See:

- o)history
- o)set

1

33.2 Variables Used

The frame mechanism uses several dollar variables.

33.2.1 Primary variables

Primary variables are those which exist solely to make the frame mechanism work.

The `$interpreterFrameName` contains a symbol which is the name of the current frame in use.

The `$interpreterFrameRing` contains a list of all of the existing frames. The first frame on the list is the “current” frame. When AXIOMsys is started directly there is only one frame named “initial”.

If the system is started under sman (using the axiom shell script, for example), there are two frames, “initial” and “frame0”. In this case, “frame0” is the current frame. This can cause subtle problems because functions defined in the axiom initialization file (`.axiom.input`) will be defined in frame “initial” but the current frame will be “frame0”. They will appear to be undefined. However, if the user does “)frame next” they can switch to the “initial” frame and see the functions correctly defined.

The `$frameMessages` variable controls when frame messages will be displayed. The variable is initially NIL. It can be set on (T) or off (NIL) using the system command:

```
)set message frame on | off
```

¹ “history” (35.4.7 p 580) “set” (46.36.1 p 805)

Setting frame messages on will output a line detailing the current frame after every output is complete.

33.2.2 Used variables

The frame collects and uses a few top level variables. These are: `$InteractiveFrame`, `$IOindex`, `$HiFiAccess`, `$HistList`, `$HistListLen`, `$HistListAct`, `$HistRecord`, `$internalHistoryTable`, and `$localExposureData`.

These variables can also be changed by the frame mechanism when the user requests changing to a different frame.

33.3 Data Structures

33.3.1 Frames and the Interpreter Frame Ring

Axiom has the notion of “frames”. A frame is a data structure which holds all the vital data from an Axiom session. There can be multiple frames and these live in a top-level variable called `$interpreterFrameRing`. This variable holds a circular list of frames. The parts of a frame and their initial, default values are:

<code>\$interpreterFrameName</code>	a string, named on creation
<code>\$InteractiveFrame</code>	(list (list nil))
<code>\$IOindex</code>	an integer, 1
<code>\$HiFiAccess</code>	<code>\$HiFiAccess</code> , see the variable description
<code>\$HistList</code>	<code>\$HistList</code> , see the variable description
<code>\$HistListLen</code>	<code>\$HistListLen</code> , see the variable description
<code>\$HistListAct</code>	<code>\$HistListAct</code> , see the variable description
<code>\$HistRecord</code>	<code>\$HistRecord</code> , see the variable description
<code>\$internalHistoryTable</code>	nil
<code>\$localExposureData</code>	a copy of <code>\$localExposureData</code>

33.4 Accessor Functions

These could be macros but we wish to export them to the API code in the algebra so we keep them as functions.

33.4.1 0th Frame Component – `frameName`

33.4.2 `defun frameName`

— `defun frameName 0` —

```
(defun frameName (frame)
  (car frame))
```

33.4.3 1st Frame Component – frameInteractive

— defun frameInteractive 0 —

```
(defun frameInteractive (frame)
  (nth 1 frame))
```

33.4.4 2nd Frame Component – frameIOIndex

— defun frameIOIndex 0 —

```
(defun frameIOIndex (frame)
  (nth 2 frame))
```

33.4.5 3rd Frame Component – frameHiFiAccess

— defun frameHiFiAccess 0 —

```
(defun frameHiFiAccess (frame)
  (nth 3 frame))
```

33.4.6 4th Frame Component – frameHistList

— defun frameHistList 0 —

```
(defun frameHistList (frame)
  (nth 4 frame))
```

33.4.7 5th Frame Component – frameHistListLen

— defun frameHistListLen 0 —

```
(defun frameHistListLen (frame)
  (nth 5 frame))
```

33.4.8 6th Frame Component – frameHistListAct

— defun frameHistListAct 0 —

```
(defun frameHistListAct (frame)
  (nth 6 frame))
```

33.4.9 7th Frame Component – frameHistRecord

— defun frameHistRecord 0 —

```
(defun frameHistRecord (frame)
  (nth 7 frame))
```

33.4.10 8th Frame Component – frameHistoryTable

— defun frameHistoryTable 0 —

```
(defun frameHistoryTable (frame)
  (nth 8 frame))
```

33.4.11 9th Frame Component – frameExposureData

— defun frameExposureData 0 —

```
(defun frameExposureData (frame)
  (nth 9 frame))
```

33.5 Functions

33.5.1 Initializing the Interpreter Frame Ring

Now that we know what a frame looks like we need a function to initialize the list of frames. This function sets the initial frame name to “initial” and creates a list of frames containing an empty frame. This list is the interpreter frame ring and is not actually circular but is managed as a circular list.

As a final step we update the world from this frame. This has the side-effect of resetting all the important global variables to their initial values.

```
[emptyInterpreterFrame p554]
[updateFromCurrentInterpreterFrame p556]
[$interpreterFrameName p??]
[$interpreterFrameRing p??]
```

— defun initializeInterpreterFrameRing —

```
(defun |initializeInterpreterFrameRing| ()
  "Initializing the Interpreter Frame Ring"
  (declare (special |$interpreterFrameName| |$interpreterFrameRing|))
  (setq |$interpreterFrameName| ' |initial|)
  (setq |$interpreterFrameRing|
    (list (|emptyInterpreterFrame| |$interpreterFrameName|)))
  (|updateFromCurrentInterpreterFrame|)
  nil)
```

33.5.2 Creating a List of all of the Frame Names

This function simply walks across the frame in the frame ring and returns a list of the name of each frame. [*\$interpreterFrameRing p??*]

— **defun frameNames 0** —

```
(defun |frameNames| ()
  "Creating a List of all of the Frame Names"
  (declare (special |$interpreterFrameRing|))
  (mapcar #'frameName |$interpreterFrameRing|))
```

33.5.3 Get Named Frame Environment (aka Interactive)

If the frame is found we return the environment portion of the frame otherwise we construct an empty environment and return it. The initial values of an empty frame are created here. This function returns a single frame that will be placed in the frame ring. [*frameInteractive p??*]

— **defun frameEnvironment** —

```
(defun |frameEnvironment| (fname)
  "Get Named Frame Environment (aka Interactive)"
  (let ((frame (|findFrameInRing| fname)))
    (if frame
      (frameInteractive frame)
      (list (list nil)))))
```

33.5.4 Create a new, empty Interpreter Frame

```
[|HiFiAccess p730|
 |HistList p??|
 |HistListLen p??|
 |HistListAct p??|
 |HistRecord p??|
 |localExposureDataDefault p694|
```

— **defun emptyInterpreterFrame 0** —

```
(defun |emptyInterpreterFrame| (name)
```

```
"Create a new, empty Interpreter Frame"
(declare (special |$HiFiAccess| |$HistList| |$HistListLen| |$HistListAct|
  |$HistRecord| |$localExposureDataDefault|))
(list name                               ; frame name
  (list (list nil))                     ; environment
  1                                     ; $IOindex
  |$HiFiAccess|
  |$HistList|
  |$HistListLen|
  |$HistListAct|
  |$HistRecord|
  nil                                  ; $internalHistoryTable
  (copy-seq |$localExposureDataDefault|))) ; $localExposureData
```

33.5.5 Collecting up the Environment into a Frame

We can collect up all the current environment information into one frame element with this call. It creates a list of the current values of the global variables and returns this as a frame element.

```
[$interpreterFrameName p??]
[$InteractiveFrame p??]
[$IOindex p??]
[$HiFiAccess p730]
[$HistList p??]
[$HistListLen p??]
[$HistListAct p??]
[$HistRecord p??]
[$internalHistoryTable p??]
[$localExposureData p694]
```

— defun createCurrentInterpreterFrame 0 —

```
(defun |createCurrentInterpreterFrame| ()
  "Collecting up the Environment into a Frame"
  (declare (special |$interpreterFrameName| |$InteractiveFrame| |$IOindex|
    |$HiFiAccess| |$HistList| |$HistListLen| |$HistListAct| |$HistRecord|
    |$internalHistoryTable| |$localExposureData|))
  (list
    |$interpreterFrameName|
    |$InteractiveFrame|
    |$IOindex|
    |$HiFiAccess|
    |$HistList|
    |$HistListLen|
```

```

|$HistListAct|
|$HistRecord|
|$internalHistoryTable|
|$localExposureData|))

```

33.5.6 Update from the Current Frame

The frames are kept on a circular list. The first element on that list is known as “the current frame”. This will initialize all of the interesting interpreter data structures from that frame.

```

[sayMessage p??]
[$interpreterFrameRing p??]
[$interpreterFrameName p??]
[$InteractiveFrame p??]
[$IOindex p??]
[$HiFiAccess p730]
[$HistList p??]
[$HistListLen p??]
[$HistListAct p??]
[$HistRecord p??]
[$internalHistoryTable p??]
[$localExposureData p694]
[$frameMessages p738]

```

— defun updateFromCurrentInterpreterFrame —

```

(defun |updateFromCurrentInterpreterFrame| ()
  "Update from the Current Frame"
  (let (tmp1)
    (declare (special |$interpreterFrameRing| |$interpreterFrameName|
      |$InteractiveFrame| |$IOindex| |$HiFiAccess| |$HistList| |$HistListLen|
      |$HistListAct| |$HistRecord| |$internalHistoryTable| |$localExposureData|
      |$frameMessages|))
    (setq tmp1 (first |$interpreterFrameRing|))
    (setq |$interpreterFrameName| (nth 0 tmp1))
    (setq |$InteractiveFrame|      (nth 1 tmp1))
    (setq |$IOindex|               (nth 2 tmp1))
    (setq |$HiFiAccess|            (nth 3 tmp1))
    (setq |$HistList|              (nth 4 tmp1))
    (setq |$HistListLen|           (nth 5 tmp1))
    (setq |$HistListAct|           (nth 6 tmp1))
    (setq |$HistRecord|            (nth 7 tmp1))
    (setq |$internalHistoryTable|  (nth 8 tmp1))
    (setq |$localExposureData|     (nth 9 tmp1))
    (when |$frameMessages|

```

```
(|sayMessage|
  '( "    Current interpreter frame is called"
    ,#(|bright| |$interpreterFrameName|))))
```

33.5.7 Find a Frame in the Frame Ring by Name

Each frame contains its name as the 0th element. We simply walk all the frames and if we find one we return it. [boot-equal p??]

```
[frameName p550]
[$interpreterFrameRing p??]
```

— defun findFrameInRing 0 —

```
(defun |findFrameInRing| (name)
  "Find a Frame in the Frame Ring by Name"
  (let (result)
    (declare (special |$interpreterFrameRing|))
    (dolist (frame |$interpreterFrameRing|)
      (when (boot-equal (frameName frame) name)
        (setq result frame)))
    result))
```

33.5.8 Update the Current Interpreter Frame

This function collects the normal contents of the world into a frame object, places it first on the frame list, and then sets the current values of the world from the frame object.

```
[createCurrentInterpreterFrame p555]
[updateFromCurrentInterpreterFrame p556]
[$interpreterFrameRing p??]
```

— defun updateCurrentInterpreterFrame —

```
(defun |updateCurrentInterpreterFrame| ()
  "Update the Current Interpreter Frame"
  (declare (special |$interpreterFrameRing|))
  (rplaca |$interpreterFrameRing| (|createCurrentInterpreterFrame|))
  (|updateFromCurrentInterpreterFrame|))
```

33.5.9 Move to the next Interpreter Frame in Ring

This function updates the current frame to make sure all of the current information is recorded. If there are more frame elements in the list then this will destructively move the current frame to the end of the list, that is, assume the frame list reads (1 2 3) this function will destructively change it to (2 3 1). [updateFromCurrentInterpreterFrame p556]

[*\$interpreterFrameRing* p??]

— **defun nextInterpreterFrame** —

```
(defun |nextInterpreterFrame| ()
  "Move to the next Interpreter Frame in Ring"
  (declare (special |$interpreterFrameRing|))
  (when (cdr |$interpreterFrameRing|)
    (setq |$interpreterFrameRing|
      (nconc (cdr |$interpreterFrameRing|) (list (car |$interpreterFrameRing|))))
    (|updateFromCurrentInterpreterFrame|)))
```

33.5.10 Change to the Named Interpreter Frame

[updateCurrentInterpreterFrame p557]

[findFrameInRing p557]

[nremove p??]

[updateFromCurrentInterpreterFrame p556]

[*\$interpreterFrameRing* p??]

— **defun changeToNamedInterpreterFrame** —

```
(defun |changeToNamedInterpreterFrame| (name)
  "Change to the Named Interpreter Frame"
  (let (frame)
    (declare (special |$interpreterFrameRing|))
    (|updateCurrentInterpreterFrame|)
    (setq frame (|findFrameInRing| name))
    (when frame
      (setq |$interpreterFrameRing|
        (cons frame (nremove |$interpreterFrameRing| frame)))
      (|updateFromCurrentInterpreterFrame|))))
```

33.5.11 Move to the previous Interpreter Frame in Ring

```
[updateCurrentInterpreterFrame p557]
[updateFromCurrentInterpreterFrame p556]
[$interpreterFrameRing p??]
```

— **defun previousInterpreterFrame** —

```
(defun |previousInterpreterFrame| ()
  "Move to the previous Interpreter Frame in Ring"
  (let (tmp1 1 b)
    (declare (special |$interpreterFrameRing|))
    (|updateCurrentInterpreterFrame|)
    (when (cdr |$interpreterFrameRing|)
      (setq tmp1 (reverse |$interpreterFrameRing|))
      (setq 1 (car tmp1))
      (setq b (nreverse (cdr tmp1)))
      (setq |$interpreterFrameRing| (nconc (cons 1 nil) b))
      (|updateFromCurrentInterpreterFrame|))))
```

33.5.12 Add a New Interpreter Frame

```
[boot-equal p??]

33.6 Frame File Messages

— Frame File Messages —

S2IZ0016

The %1b system command takes arguments but no options.

S2IZ0017

%1b is not a valid frame name

S2IZ0018

You must provide a name for the new frame.

S2IZ0019

You cannot use the name %1b for a new frame because an existing frame already has that name.

S2IZ0020

There is only one frame active and therefore that cannot be closed.
Furthermore, the frame name you gave is not the name of the current frame.
The current frame is called %1b .

S2IZ0021

The current frame is the only active one. Issue %b)clear all %d to clear its contents.

S2IZ0022

There is no frame called %1b and so your command cannot be processed.

S2IZ0024

The names of the existing frames are: %1 %1
The current frame is the first one listed.

S2IZ0073

%b)frame import %d must be followed by the frame name. The names of objects in that frame can then optionally follow the frame name. For example,
%ceon %b)frame import calculus %d %ceoff
imports all objects in the %b calculus %d frame, and
%ceon %b)frame import calculus epsilon delta %d %ceoff

imports the objects named %b epsilon %d and %b delta %d from the frame %b calculus %d .

Please note that if the current frame contained any information about objects with these names, then that information would be cleared before the import took place.

S2IZ0074

You cannot import anything from the frame %1b because that is not the name of an existing frame.

S2IZ0075

You cannot import from the current frame (nor is there a need!).

S2IZ0076

User verification required:

do you really want to import everything from the frame %1b ?

If so, please enter %b y %d or %b yes %d :

S2IZ0077

On your request, AXIOM will not import everything from frame %1b.

S2IZ0078

Import from frame %1b is complete. Please issue %b)display all %d if you wish to see the contents of the current frame.

S2IZ0079

AXIOM cannot import %1b from frame %2b because it cannot be found.

Chapter 34

)help help page Command

34.1 help help page man page

— help.help —

```
=====
A.12. )help
=====
```

User Level Required: interpreter

Command Syntax:

-)help
-)help commandName
-)help syntax

Command Description:

This command displays help information about system commands. If you issue

```
)help
```

then this very text will be shown. You can also give the name or abbreviation of a system command to display information about it. For example,

```
)help clear
```

will display the description of the)clear system command.

The command

)help syntax

will give further information about the Axiom language syntax.

All this material is available in the AXIOM User Guide and in HyperDoc. In HyperDoc, choose the Commands item from the Reference menu.

```
=====
A.1.  Introduction
=====
```

System commands are used to perform AXIOM environment management. Among the commands are those that display what has been defined or computed, set up multiple logical AXIOM environments (frames), clear definitions, read files of expressions and commands, show what functions are available, and terminate AXIOM.

Some commands are restricted: the commands

```
)set userlevel interpreter
)set userlevel compiler
)set userlevel development
```

set the user-access level to the three possible choices. All commands are available at development level and the fewest are available at interpreter level. The default user-level is interpreter. In addition to the)set command (discussed in description of command)set) you can use the HyperDoc settings facility to change the user-level. Click on [Settings] here to immediately go to the settings facility.

Each command listing begins with one or more syntax pattern descriptions plus examples of related commands. The syntax descriptions are intended to be easy to read and do not necessarily represent the most compact way of specifying all possible arguments and options; the descriptions may occasionally be redundant.

All system commands begin with a right parenthesis which should be in the first available column of the input line (that is, immediately after the input prompt, if any). System commands may be issued directly to AXIOM or be included in .input files.

A system command argument is a word that directly follows the command name and is not followed or preceded by a right parenthesis. A system command option follows the system command and is directly preceded by a right parenthesis. Options may have arguments: they directly follow the option. This example may make it easier to remember what is an option and what is an argument:

```
)syscmd arg1 arg2 )opt1 opt1arg1 opt1arg2 )opt2 opt2arg1 ...
```

In the system command descriptions, optional arguments and options are enclosed in brackets ('[' and ']'). If an argument or option name is in italics, it is meant to be a variable and must have some actual value substituted for it when the system command call is made. For example, the syntax pattern description

```
)read fileName [quietly]
```

would imply that you must provide an actual file name for *fileName* but need not use the *)quietly* option. Thus

```
)read matrix.input
```

is a valid instance of the above pattern.

System command names and options may be abbreviated and may be in upper or lower case. The case of actual arguments may be significant, depending on the particular situation (such as in file names). System command names and options may be abbreviated to the minimum number of starting letters so that the name or option is unique. Thus

```
)s Integer
```

is not a valid abbreviation for the *)set* command, because both *)set* and *)show* begin with the letter 's'. Typically, two or three letters are sufficient for disambiguating names. In our descriptions of the commands, we have used no abbreviations for either command names or options.

In some syntax descriptions we use a vertical line '|' to indicate that you must specify one of the listed choices. For example, in

```
)set output fortran on | off
```

only on and off are acceptable words for following boot. We also sometimes use '...' to indicate that additional arguments or options of the listed form are allowed. Finally, in the syntax descriptions we may also list the syntax of related commands.

Chapter 35

)history help page Command

35.1 history help page man page

— history.help —

```
=====
A.13. )history
=====
```

User Level Required: interpreter

Command Syntax:

-)history)on
-)history)off
-)history)write historyInputFileName
-)history)show [n] [both]
-)history)save savedHistoryName
-)history)restore [savedHistoryName]
-)history)reset
-)history)change n
-)history)memory
-)history)file
- %
- %% (n)
-)set history on | off

Command Description:

The history facility within AXIOM allows you to restore your environment to that of another session and recall previous computational results. Additional commands allow you to review previous input lines and to create an .input

file of the lines typed to AXIOM.

AXIOM saves your input and output if the history facility is turned on (which is the default). This information is saved if either of

```
)set history on
)history )on
```

has been issued. Issuing either

```
)set history off
)history )off
```

will discontinue the recording of information.

Whether the facility is disabled or not, the value of % in AXIOM always refers to the result of the last computation. If you have not yet entered anything, % evaluates to an object of type Variable('%'). The function %% may be used to refer to other previous results if the history facility is enabled. In that case, %(n) is the output from step n if n > 0. If n < 0, the step is computed relative to the current step. Thus %(-1) is also the previous step, %(-2), is the step before that, and so on. If an invalid step number is given, AXIOM will signal an error.

The environment information can either be saved in a file or entirely in memory (the default). Each frame (description of command)frame) has its own history database. When it is kept in a file, some of it may also be kept in memory for efficiency. When the information is saved in a file, the name of the file is of the form FRAME.ahx where "FRAME" is the name of the current frame. The history file is placed in the current working directory (see description of command)cd). Note that these history database files are not text files (in fact, they are directories themselves), and so are not in human-readable format.

The options to the)history command are as follows:

```
)change n
    will set the number of steps that are saved in memory to n. This option
    only has effect when the history data is maintained in a file. If you
    have issued )history )memory (or not changed the default) there is no
    need to use )history )change.

)on
    will start the recording of information. If the workspace is not empty,
    you will be asked to confirm this request. If you do so, the workspace
    will be cleared and history data will begin being saved. You can also
    turn the facility on by issuing )set history on.

)off
    will stop the recording of information. The )history )show command will
```

not work after issuing this command. Note that this command may be issued to save time, as there is some performance penalty paid for saving the environment data. You can also turn the facility off by issuing `)set history off`.

`)file`
indicates that history data should be saved in an external file on disk.

`)memory`
indicates that all history data should be kept in memory rather than saved in a file. Note that if you are computing with very large objects it may not be practical to keep this data in memory.

`)reset`
will flush the internal list of the most recent workspace calculations so that the data structures may be garbage collected by the underlying Lisp system. Like `)history)change`, this option only has real effect when history data is being saved in a file.

`)restore [savedHistoryName]`
completely clears the environment and restores it to a saved session, if possible. The `)save` option below allows you to save a session to a file with a given name. If you had issued `)history)save jacobi` the command `)history)restore jacobi` would clear the current workspace and load the contents of the named saved session. If no saved session name is specified, the system looks for a file called `last.axh`.

`)save savedHistoryName`
is used to save a snapshot of the environment in a file. This file is placed in the current working directory (see description of command `)cd`). Use `)history)restore` to restore the environment to the state preserved in the file. This option also creates an input file containing all the lines of input since you created the workspace frame (for example, by starting your AXIOM session) or last did a `)clear all` or `)clear completely`.

`)show [n] [both]`
can show previous input lines and output results. `)show` will display up to twenty of the last input lines (fewer if you haven't typed in twenty lines). `)show n` will display up to `n` of the last input lines. `)show both` will display up to five of the last input lines and output results. `)show n both` will display up to `n` of the last input lines and output results.

`)write historyInputFile`
creates an `.input` file with the input lines typed since the start of the session/frame or the last `)clear all` or `)clear completely`. If `historyInputFileName` does not contain a period (`'.'`) in the filename, `.input` is appended to it. For example, `)history)write chaos` and `)history)write chaos.input` both write the input lines to a file called `chaos.input` in your current working directory. If you issued one or more

`)undo` commands, `)history` `)write` eliminates all input lines backtracked over as a result of `)undo`. You can edit this file and then use `)read` to have AXIOM process the contents.

Also See:

- o `)frame`
- o `)read`
- o `)set`
- o `)undo`

1

History recording is done in two different ways:

- all changes in variable bindings (i.e. previous values) are written to `$HistList`, which is a circular list
- all new bindings (including the binding to `%`) are written to a file called `histFileName()` one older session is accessible via the file `$oldHistFileName()`

35.2 Initialized history variables

The following global variables are used:

`$HistList`, `$HistListLen` and `$HistListAct` which is the actual number of “undoable” steps)

`$HistRecord` collects the input line, all variable bindings and the output of a step, before it is written to the file `histFileName()`.

`$HiFiAccess` is a flag, which is reset by `)history` `)off`

The result of step `n` can be accessed by `%n`, which is translated into a call of `fetchOutput(n)`. The `updateHist` is called after every interpreter step. The `putHist` function records all changes in the environment to `$HistList` and `$HistRecord`.

35.4.9 defun setHistoryCore

We case on the inCore argument value

If history is already on and is kept in the same location as requested (file or memory)

then complain.

If history is not in use then start using the file or memory as requested. This is done by simply setting the `$useInternalHistoryTable` to the requested value, where T means use memory and NIL means use a file. We tell the user.

If history should be in memory, that is `inCore` is not NIL, and the history file already contains information we read the information from the file, store it in memory, and erase the history file. We modify `$useInternalHistoryTable` to T to indicate that we're maintaining the history in memory and tell the user.

Otherwise history must be on and in memory. We erase any old history file and then write the in-memory history to a new file

35.6 History File Messages

— History File Messages —

S2IH0001

You have not reached step %1b yet, and so its value cannot be supplied.

S2IH0002

Cannot supply value for step %1b because 1 is the first step.

S2IH0003

Step %1b has no value.

S2IH0004

The history facility is not on, so you cannot use %b %% %d .

S2IH0006

You have not used the correct syntax for the %b history %d command.

Issue %b)help history %d for more information.

S2IH0007

The history facility is already on.

S2IH0008

The history facility is now on.

S2IH0009

Turning on the history facility will clear the contents of the workspace.

Please enter %b y %d or %b yes %d if you really want to do this:

S2IH0010

The history facility is still off.

S2IH0011

The history facility is already off.

S2IH0012

The history facility is now off.

S2IH0013

The history facility is not on, so the .input file containing your user input cannot be created.

S2IH0014

Edit %b %1 %d to see the saved input lines.

S2IH0015

The argument %b n %d for %b)history)change n must be a nonnegative integer and your argument, %1b , is not one.

S2IH0016

The history facility is not on, so no information can be saved.

S2IH0018

The saved history file is %1b .

S2IH0019

There is no history file, so value of step %1b is undefined.

S2IH0022

No history information had been saved yet.

S2IH0023

%1b is not a valid filename for the history file.
S2IH0024
History information cannot be restored from %1b because the file does not exist.
S2IH0025
The workspace has been successfully restored from the history file %1b .
S2IH0026
The history facility command %1b cannot be performed because the history facility is not on.
S2IH0027
A value containing a %1b is being saved in a history file or a compiled input file INLIB. This type is not yet usable in other history operations. You might want to issue %b)history)off %d
S2IH0029
History information is already being maintained in an external file (and not in memory).
S2IH0030
History information is already being maintained in memory (and not in an external file).
S2IH0031
When the history facility is active, history information will be maintained in a file (and not in an internal table).
S2IH0032
When the history facility is active, history information will be maintained in memory (and not in an external file).
S2IH0034
Missing element in internal history table.
S2IH0035
Can't save the value of step number %1b. You can re-generate this value by running the input file %2b.
S2IH0036
The value specified cannot be saved to a file.
S2IH0037
You must specify a file name to the history save command
S2IH0038
You must specify a file name to the history write command

Chapter 36

)include help page Command

36.1 include help page man page

— include.help —

User Level Required: interpreter

Command Syntax:

```
)include filename
```

Command Description:

The `)include` command can be used in `.input` files to place the contents of another file inline with the current file. The path can be an absolute or relative pathname.

36.2 Functions

36.2.1 defun ncloopInclude1

[ncloopIncFileName p620]

[ncloopInclude p620]

— defun ncloopInclude1 —

```
(defun |ncloopInclude1| (name n)
  (let (a)
    (if (setq a (|ncloopIncFileName| name))
        (|ncloopInclude| a n)
        n)))
```

36.2.2 Returns the first non-blank substring of the given string

[incFileName p620]
[concat p1049]

— defun ncloopIncFileName —

```
(defun |ncloopIncFileName| (string)
  "Returns the first non-blank substring of the given string"
  (let (fn)
    (unless (setq fn (|incFileName| string))
      (write-line (concat string " not found"))))
  fn))
```

36.2.3 Open the include file and read it in

The ncloopInclude0 function is part of the parser and lives in int-top.boot. [ncloopInclude0 p73]

— defun ncloopInclude —

```
(defun |ncloopInclude| (name n)
  "Open the include file and read it in"
  (with-open-file (st name) (|ncloopInclude0| st name n)))
```

36.2.4 Return the include filename

Given a string we return the first token from the string which is the first non-blank substring. [incBiteOff p621]

— defun incFileName —

```
(defun |incFileName| (x)
  "Return the include filename"
  (car (|incBiteOff| x)))
```

36.2.5 Return the next token

Takes a sequence and returns the a list of the first token and the remaining string characters. If there are no remaining string characters the second string is of length 0. Effectively it "bites off" the first token in the string. If the string only 0 or more blanks it returns nil.

— **defun incBiteOff** —

```
(defun |incBiteOff| (x)
  "Return the next token"
  (let (blank nonblank)
    (setq x (string x))
    (when (setq nonblank (position #\space x :test-not #'char=))
      (setq blank (position #\space x :start nonblank))
      (if blank
        (list (subseq x nonblank blank) (subseq x blank))
        (list (subseq x nonblank) ""))))))
```

Chapter 37

)library help page Command

37.1 library help page man page

— library.help —

```
=====
A.14. )library
=====
```

User Level Required: interpreter

Command Syntax:

-)library libName1 [libName2 ...]
-)library)dir dirName
-)library)only objName1 [objlib2 ...]
-)library)noexpose

Command Description:

This command replaces the)load system command that was available in AXIOM releases before version 2.0. The)library command makes available to AXIOM the compiled objects in the libraries listed.

For example, if you)compile dopler.spad in your home directory, issue)library dopler to have AXIOM look at the library, determine the category and domain constructors present, update the internal database with various properties of the constructors, and arrange for the constructors to be automatically loaded when needed. If the)noexpose option has not been given, the constructors will be exposed (that is, available) in the current frame.

If you compiled a file you will have an NRLIB present, for example,

DOPLER.NRLIB, where DOPLER is a constructor abbreviation. The command)library DOPLER will then do the analysis and database updates as above.

To tell the system about all libraries in a directory, use)library)dir dirName where dirName is an explicit directory. You may specify ‘.’ as the directory, which means the current directory from which you started the system or the one you set via the)cd command. The directory name is required.

You may only want to tell the system about particular constructors within a library. In this case, use the)only option. The command)library dopler)only Test1 will only cause the Test1 constructor to be analyzed, autoloaded, etc..

Finally, each constructor in a library are usually automatically exposed when the)library command is used. Use the)noexpose option if you not want them exposed. At a later time you can use)set expose add constructor to expose any hidden constructors.

Note for AXIOM beta testers: At various times this command was called)local and)with before the name)library became the official name.

Chapter 38

)lisp help page Command

38.1 lisp help page man page

— lisp.help —

```
=====
A.15. )lisp
=====
```

User Level Required: development

Command Syntax:

-)lisp [lispExpression]

Command Description:

This command is used by AXIOM system developers to have single expressions evaluated by the Lisp system on which AXIOM is built. The `lispExpression` is read by the Lisp reader and evaluated. If this expression is not complete (unbalanced parentheses, say), the reader will wait until a complete expression is entered.

Since this command is only useful for evaluating single expressions, the `)fin` command may be used to drop out of AXIOM into Lisp.

Also See:

- o)system
- o)boot
- o)fin

¹

38.2 Functions

This command is in the list of `$noParseCommands` 19.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 19.2.1

¹ “system” (?? p ??) “boot” (5.1.8 p 25) “fin” (32.1.1 p 546)

Chapter 39

)load help page Command

39.1 load help page man page

— load.help —

```
=====
A.16. )load
=====
```

User Level Required: interpreter

Command Description:

This command is obsolete. Use)library instead.

—————

39.1.1 defun The)load command (obsolete)

We keep this command around in case anyone has the original Axiom book. [sayKeyedMsg p329]

— defun load —

```
(defun |load| (ignore)
  (declare (ignore ignore))
  (|sayKeyedMsg| 'S2IU0003 nil))
```

—————

Chapter 40

)ltrace help page Command

40.1 ltrace help page man page

— ltrace.help —

```
=====
A.17. )ltrace
=====
```

User Level Required: development

Command Syntax:

This command has the same arguments as options as the)trace command.

Command Description:

This command is used by AXIOM system developers to trace Lisp or BOOT functions. It is not supported for general use.

Also See:

- o)boot

)pquit help page Command

41.1 pquit help page man page

— pquit.help —

```
=====
A.18. )pquit
=====
```

User Level Required: interpreter

Command Syntax:

-)pquit

Command Description:

This command is used to terminate AXIOM and return to the operating system. Other than by redoing all your computations or by using the)history)restore command to try to restore your working environment, you cannot return to AXIOM in the same state.

)pquit differs from the)quit in that it always asks for confirmation that you want to terminate AXIOM (the ‘p’ is for ‘protected’). When you enter the)pquit command, AXIOM responds

Please enter y or yes if you really want to leave the interactive
environment and return to the operating system:

If you respond with y or yes, you will see the message

You are now leaving the AXIOM interactive environment.

Issue the command `axiom` to the operating system to start a new session.

and AXIOM will terminate and return you to the operating system (or the environment from which you invoked the system). If you responded with something other than `y` or `yes`, then the message

You have chosen to remain in the AXIOM interactive environment.

will be displayed and, indeed, AXIOM would still be running.

  "The top level pquit command"
  (|pquitSpad2Cmd|))
```

41.2.2 The top level `pquit` command handler

[`quitSpad2Cmd` p636]

[\$`quitCommandType` p797]

— **defun `pquitSpad2Cmd`** —

¹ “`fin`” (32.1.1 p 546) “`history`” (35.4.7 p 580) “`close`” (25.2.2 p 508) “`quit`” (42.2.1 p 636) “`system`” (?? p ??)

```
(defun |pquitSpad2Cmd| ()  
  "The top level pquit command handler"  
  (let ((|quitCommandType| ' |protected|))  
    (declare (special |quitCommandType|))  
    (|quitSpad2Cmd|)))
```

This command is in the list of `$noParseCommands` 19.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 19.2.1

Chapter 42

)quit help page Command

42.1 quit help page man page

— quit.help —

```
=====
A.19. )quit
=====
```

User Level Required: interpreter

Command Syntax:

-)quit
-)set quit protected | unprotected

Command Description:

This command is used to terminate AXIOM and return to the operating system. Other than by redoing all your computations or by using the)history)restore command to try to restore your working environment, you cannot return to AXIOM in the same state.

)quit differs from the)pquit in that it asks for confirmation only if the command

)set quit protected

has been issued. Otherwise,)quit will make AXIOM terminate and return you to the operating system (or the environment from which you invoked the system).

The default setting is)set quit protected so that)quit and)pquit behave in

the same way. If you do issue

```
)set quit unprotected
```

we suggest that you do not (somehow) assign)quit to be executed when you press, say, a function key.

Chapter 43

)read help page Command

43.1 read help page man page

— read.help —

```
=====
A.20. )read
=====
```

User Level Required: interpreter

Command Syntax:

-)read [fileName]
-)read [fileName] []quiet] []ifthere]

Command Description:

This command is used to read .input files into AXIOM. The command

)read matrix.input

will read the contents of the file matrix.input into AXIOM. The ‘.input’ file extension is optional. See the AXIOM User Guide index for more information about .input files.

This command remembers the previous file you edited, read or compiled. If you do not specify a file name, the previous file will be read.

The)ifthere option checks to see whether the .input file exists. If it does not, the)read command does nothing. If you do not use this option and the file does not exist, you are asked to give the name of an existing .input

file.

The `)quiet` option suppresses output while the file is being read.

Also See:

- o `)compile`
- o `)edit`
- o `)history`

Chapter 44

)regress help page Command

44.1 regress help page man page

— regress.help —

```
=====
A.18. )regress
=====
```

User Level Required: interpreter

Command Syntax:

-)regress fileName

Command Description:

The regress command will run the regress function that was compiled as part of the lisp image build process. This function expects an input filename, possibly containing a path prefix.

If the filename contains a period then we consider it a fully formed filename, otherwise we append ‘.output’, which is the default file extension.

```
)regress matrix
)regress matrix.output
)regress /path/to/file/matrix
)regress /path/to/file/matrix.output
```

will test the contents of the file matrix.output.

The idea behind regression testing is to check that the results we currently get match the results we used to get. In order to do that we create input files with a special comment format that contains the prior results. These are easy to create as all you need to do is run the Axiom function, capture the results, and turn them input specially formed comments using the `--` comment.

A regression file caches the result of an Axiom function so we can automate the testing process. It is a file of many tests, each with their own output.

The regression file format uses the Axiom `--` comment syntax to keep a copy of the expected output from an Axiom command. This expected output is compared character by character against the actual output.

The regression file is broken into numbered blocks, delimited by a `--S` for the beginning and a `--E` for the end. The total number of blocks is also given so missing or failed tests also raise an error.

There are 4 special kinds of `--` comments in regression files:

<code>--S n of M</code>	this is test n of M tests in this file
<code>--E n</code>	this marks the end of test n
<code>--R any output</code>	this marks the actual expected output line
<code>--I any output</code>	this line is compared but ignored

A regression test file looks like:

```
)set break resume
)spool foo.output
)set message type off
)clear all

--S 1 of 3
2+3
--R
--R      this is the exact Axiom output
--R (1)  5
--E 1

--S 2 of 3
2+3
--R
--R      this should fail to match
--R (2)  7
--E 2

--S 3 of 3
2+3
--R
--R      this fails to match but we
--I (3)  7      use --I to ignore this line
--E 3
```

We can now run this file with

```
)read foo.input
```

Note that when this file is run it will create a spool file called "foo.output" because of the lines:

```
)spool foo.output
)spool
```

The "foo.output" file contains the console image of the result. It will look like:

```
Starts dribbling to foo.output (2012/2/28, 12:25:7).
)set message type off
)clear all

--S 1 of 3
2+3

      (1)  5
--R
--R      (1)  5
--E 1

--S 2 of 3
2+3

      (2)  5
--R
--R      (2)  7
--E 2

--S 3 of 3
2+3

      (3)  5
--R
--R      (3)  7
--E 3

)spool
```

This "foo.output" file can now be checked using the)regress command.

When we run the)regress foo.output we see;

```
testing foo
passed foo 1 of 3
```

```

MISMATCH
expected:"  (2)  7"
      got:"  (2)  5"
FAILED foo  2 of 2
passed foo  3 of 3
regression result FAILED 1 of 3 stanzas file foo

```

Tests either pass or fail. A passing test generates the message:

```
passed foo  1 of 3
```

A failing test will give a reversed printout of the expected vs actual output as well as a FAILED message, as in:

```

MISMATCH
expected:"  (2)  7"
      got:"  (2)  5"
FAILED foo  2 of 3

```

The last line of output is a summary:

```
regression result FAILED 1 of 3 stanzas file foo
```

— defun regress —

    (if (probe-file outfile)
        (regress outfile)
        (format t (concatenate 'string outfile "% file not found")))))

```

Chapter 45

)savesystem help page Command

45.1 savesystem help page man page

— savesystem.help —

```
=====
A.8. )savesystem
=====
```

User Level Required: interpreter

Command Syntax:

```
- )savesystem filename
```

Command Description:

This command is used to save an AXIOM image to disk. This creates an executable file which, when started, has everything loaded into it that was there when the image was saved. Thus, after executing commands which cause the loading of some packages, the command:

```
)savesystem /tmp/savesys
```

will create an image that can be restarted with the UNIX command:

```
axiom -ws /tmp/savesys
```

This new system will not need to reload the packages and domains that were already loaded when the system was saved.

There is currently a restriction that only systems started with the command "AXIOMsys" may be saved.

45.1.1 defun The)savesystem command

[helpSpad2Cmd p570]

[spad-save p987]

— defun savesystem —

```
(defun |savesystem| (arg)
  (if (or (not (eq1 (|#| arg) 1)) (null (symbolp (car arg))))
      (|helpSpad2Cmd| '(|savesystem|))
      (spad-save (symbol-name (car arg)))))
```

Chapter 46

)set help page Command

46.1 set help page man page

— set.help —

```
=====
A.21. )set
=====
```

User Level Required: interpreter

Command Syntax:

-)set
-)set label1 [... labelN]
-)set label1 [... labelN] newValue

Command Description:

The)set command is used to view or set system variables that control what messages are displayed, the type of output desired, the status of the history facility, the way AXIOM user functions are cached, and so on. Since this collection is very large, we will not discuss them here. Rather, we will show how the facility is used. We urge you to explore the)set options to familiarize yourself with how you can modify your AXIOM working environment. There is a HyperDoc version of this same facility available from the main HyperDoc menu. Click [\[here\]](#) to go to it.

The)set command is command-driven with a menu display. It is tree-structured. To see all top-level nodes, issue)set by itself.

)set

Variables with values have them displayed near the right margin. Subtrees of selections have ‘‘...’’ displayed in the value field. For example, there are many kinds of messages, so issue `)set message` to see the choices.

```
)set message
```

The current setting for the variable that displays whether computation times are displayed is visible in the menu displayed by the last command. To see more information, issue

```
)set message time
```

This shows that time printing is on now. To turn it off, issue

```
)set message time off
```

As noted above, not all settings have so many qualifiers. For example, to change the `)quit` command to being unprotected (that is, you will not be prompted for verification), you need only issue

```
)set quit unprotected
```

Also See:

- o `)quit`

1

46.2 Overview

This section contains tree of information used to initialize the `)set` command in the interpreter. The current list is:

Variable	Description	Current Value

<code>compile</code>	Library compiler options	...
<code>breakmode</code>	execute break processing on error	break
<code>expose</code>	control interpreter constructor exposure	...
<code>functions</code>	some interpreter function options	...
<code>fortran</code>	view and set options for FORTRAN output	...
<code>kernel</code>	library functions built into the kernel for efficiency	...
<code>hyperdoc</code>	options in using HyperDoc	...

¹ “quit” (42.2.1 p 636)

help	view and set some help options	...
history	save workspace values in a history file	on
messages	show messages for various system features	...
naglink	options for NAGLink	...
output	view and set some output options	...
quit	protected or unprotected quit	unprotected
streams	set some options for working with streams	...
system	set some system development variables	...
userlevel	operation access level of system user	development

Variables with current values of ... have further sub-options.
 For example, issue `)set system` to see what the options are
 for system. For more information, issue `)help set .`

46.3 Variables Used

46.4 Functions

46.4.1 Initialize the set variables

The argument `settree` is initially the `$setOption` variable. The fourth element is a union-style switch symbol. The fifth element is usually a variable to set. The sixth element is a subtree to recurse for the `TREE` switch. The seventh element is usually the default value. For more detailed explanations see the list structure section 46.5. [sayMSG p331]

    (t x)))
```

46.5 The list structure

The structure of each list item consists of 7 items. Consider this example:

```
(userlevel
  "operation access level of system user"
  interpreter
  LITERALS
  $UserLevel
  (interpreter compiler development)
  development)
```

The list looks like (the names in bold are accessor names that can be found in **property.lisp.pamphlet**[1]. Look for "setName".):

1 *Name* the keyword the user will see. In this example the user would say ")set output userlevel".

2 *Label* the message the user will see. In this example the user would see "operation access level of system user".

3 *Level* the level where the command will be accepted. There are three levels: interpreter, compiler, development. These commands are restricted to keep the user from causing damage.

4 Type a symbol, one of **FUNCTION**, **INTEGER**, **STRING**, **LITERALS**, **FILENAME** or **TREE**.

5 *Var*

FUNCTION is the function to call

INTEGER is the variable holding the current user setting.

STRING is the variable holding the current user setting.

LITERALS variable which holds the current user setting.

FILENAME is the variable that holds the current user setting.

TREE

6 *Leaf*

FUNCTION is the list of all possible values

INTEGER is the range of possible values

STRING is a list of all possible values

LITERALS is a list of all of the possible values

FILENAME is the function to check the filename

TREE

7 *Def* is the default value

FUNCTION is the default setting

INTEGER is the default setting

STRING is the default setting

LITERALS is the default setting

FILENAME is the default value

TREE

46.6 breakmode

----- The breakmode Option -----

Description: execute break processing on error

The breakmode option may be followed by any one of the following:

```
nobreak
-> break
query
resume
```

```
fastlinks
quit
```

The current setting is indicated.

46.6.1 defvar \$BreakMode

— initvars —

```
(defvar |$BreakMode| ' |nobreak| "execute break processing on error")
```

—————

— breakmode —

```
(|breakmode|
 "execute break processing on error"

 LITERALS
 |$BreakMode|
 (|nobreak| |break| |query| |resume| |fastlinks| |quit|)
 |nobreak|) ; needed to avoid possible startup looping
```

—————

46.7 debug

Current Values of debug Variables

Variable	Description	Current Value

lambdatype	Show type information for #1 syntax	off
dalymode	Interpret leading open paren as lisp	off

— debug —

```
(|debug|
 "debug options"
 |interpreter|
 TREE
 |novar|
```

```
(
\getchunk{debuglambdtype}
\getchunk{debugdalymode}
))
```

46.8 debug lambda type

----- The lambdtype Option -----

Description: Show type information for #1 syntax

46.8.1 defvar \$lambdtype

— initvars —

```
(defvar $lambdtype nil "show type information for #1 syntax")
```

— debuglambdtype —

```
(|lambdtype|
"show type information for #1 syntax"
|interpreter|
LITERALS
$lambdtype
(|on| |off|)
|off|)
```

46.9 debug dalymode

The `$dalymode` variable is used in a case statement in `intloopReadConsole`. This variable can be set to any non-nil value. When not nil the interpreter will send any line that begins with an “(” to be sent to the underlying lisp. This is useful for debugging Axiom. The normal value of this variable is NIL.

This variable was created as an alternative to prefixing every lisp command with `)lisp`. When doing a lot of debugging this is tedious and error prone. This variable was created to shortcut

that process. Clearly it breaks some semantics of the language accepted by the interpreter as parens are used for grouping expressions.

----- The dalymode Option -----

Description: Interpret leading open paren as lisp

46.9.1 defvar \$dalymode

— initvars —

```
(defvar $dalymode nil "Interpret leading open paren as lisp")
```

— debugdalymode —

```
(|dalymode|
  "Interpret leading open paren as lisp"
  |interpreter|
  LITERALS
  $dalymode
  (|on| |off|)
  |off|)
```

46.10 compile

Current Values of compiler Variables

Variable	Description	Current Value
output	library in which to place compiled code	
input	controls libraries from which to load compiled code	

— compile —

```
(|compiler|
  "Library compiler options")
```

```

|interpreter|
TREE
|novar|

  (declare (special input-libraries))
  (setq input-libraries (delete (truename lib) input-libraries :test #'equal)))
```

46.17 expose

----- The expose Option -----

Description: control interpreter constructor exposure

The following groups are explicitly exposed in the current frame (called initial):

```
        basic
categories
        naglink
        anna
```

The following constructors are explicitly exposed in the current frame:

there are no explicitly exposed constructors

The following constructors are explicitly hidden in the current frame:

there are no explicitly hidden constructors

When)set expose is followed by no arguments, the information you now see is displayed. When followed by the initialize argument, the exposure group data in the file interp.exposed is read and is then available. The arguments add and drop are used to add or drop exposure groups or explicit constructors from the local frame exposure data. Issue

)set expose add or)set expose drop
for more information.

— expose —

```
(|expose|
  "control interpreter constructor exposure"
  |interpreter|
  FUNCTION
  |setExpose|
  NIL
  |htSetExpose|)
```

46.18 Variables Used

NOTE: If you add new algebra you must also update this list otherwise the new algebra won't be loaded by the interpreter when needed.

46.21 functions cache

----- The cache Option -----

Description: number of function results to cache

)set functions cache is used to tell AXIOM how many values computed by interpreter functions should be saved. This can save quite a bit of time in recursive functions, though one must consider that the cached values will take up (perhaps valuable) room in the workspace.

The value given after cache must either be the word all or a positive integer. This may be followed by any number of function names whose cache sizes you wish to so set. If no functions are given, the default cache size is set.

Examples:)set fun cache all
)set fun cache 10 f g Legendre

In general, functions will cache no returned values.

```

46.31.3 algebra

----- The algebra Option -----

Description: display output in algebraic form

)set output algebra is used to tell AXIOM to turn algebra-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax:)set output algebra <arg>

where arg can be one of

on	turn algebra printing on (default state)
off	turn algebra printing off
console	send algebra output to screen (default state)
fp<.fe>	send algebra output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .spout.

If you wish to send the output to a file, you may need to issue this command twice: once with on and once with the file name. For example, to send algebra output to the file polymer.spout, issue the two commands

```
)set output algebra on
)set output algebra polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the)cd system command.
The current setting is: On:CONSOLE

46.31.11 fortran

----- The fortran Option -----

Description: create output in FORTRAN format

)set output fortran is used to tell AXIOM to turn FORTRAN-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Also See:)set fortran

Syntax:)set output fortran <arg>

where `arg` can be one of

<code>on</code>	turn FORTRAN printing on
<code>off</code>	turn FORTRAN printing off (default state)
<code>console</code>	send FORTRAN output to screen (default state)
<code>fp<.fe></code>	send FORTRAN output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .sfort.

If you wish to send the output to a file, you must issue this command twice: once with `on` and once with the file name. For example, to send FORTRAN output to the file `polymer.sfort`, issue the two commands

```
)set output fortran on
)set output fortran polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the `)cd` system command. The current setting is: `Off:CONSOLE`

46.31.31 openmath

----- The openmath Option -----

Description: create output in OpenMath style

)set output tex is used to tell AXIOM to turn OpenMath output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

```
Syntax:  )set output tex <arg>
         where arg can be one of
         on          turn OpenMath printing on
         off         turn OpenMath printing off (default state)
         console     send OpenMath output to screen (default state)
         fp<.fe>      send OpenMath output to file with file prefix fp
                     and file extension .fe. If not given,
                     .fe defaults to .sopen.
```

If you wish to send the output to a file, you must issue this command twice: once with `on` and once with the file name. For example, to send OpenMath output to the file `polymer.sopen`, issue the two commands

```
)set output openmath on
)set output openmath polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the `)cd` system command. The current setting is: `Off:CONSOLE`

46.31.36 script

----- The script Option -----

Description: display output in SCRIPT formula format

)set output script is used to tell AXIOM to turn IBM Script formula-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax:)set output script <arg>
 where arg can be one of
 on turn IBM Script formula printing on
 off turn IBM Script formula printing off
 (default state)
 console send IBM Script formula output to screen
 (default state)
 fp<.fe> send IBM Script formula output to file with file
 prefix fp and file extension .fe. If not given,
 .fe defaults to .sform.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send IBM Script formula output to the file polymer.sform, issue the two commands

```
)set output script on
)set output script polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the)cd system command. The current setting is: Off:CONSOLE

Description: create output in TeX style

)set output tex is used to tell AXIOM to turn TeX-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax:)set output tex <arg>

where arg can be one of

on	turn TeX printing on
off	turn TeX printing off (default state)
console	send TeX output to screen (default state)
fp<.fe>	send TeX output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .stex.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send TeX output to the file polymer.stex, issue the two commands

```
)set output tex on
)set output tex polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the `)cd` system command.
The current setting is: Off:CONSOLE

46.36.2 defun set1

This function will be called with the top level arguments to)set. For instance, given the command

```
)set break break
```

this function gets

```
(set1 (|break| |break|) ....)
```

and given the command

```
)set mes auto off
```

this function gets

```
(set1 (|mes| |auto| |off|) ....)
```

which, because “message” is a TREE, generates the recursive call:

```
(set1 (|auto| |off|) <the message subtree>)
```

The “autoload” subtree is a FUNCTION (printLoadMessages), which gets called with %describe% [displaySetVariableSettings p655]

)show help page Command

47.1 show help page man page

— show.help —

```
=====
A.22. )show
=====
```

User Level Required: interpreter

Command Syntax:

-)show nameOrAbbrev
-)show nameOrAbbrev)operations
-)show nameOrAbbrev)attributes

Command Description:

This command displays information about AXIOM domain, package and category constructors. If no options are given, the)operations option is assumed. For example,

```
)show POLY
)show POLY )operations
)show Polynomial
)show Polynomial )operations
```

each display basic information about the Polynomial domain constructor and then provide a listing of operations. Since Polynomial requires a Ring (for example, Integer) as argument, the above commands all refer to a unspecified ring R. In the list of operations, \$ means Polynomial(R).

The basic information displayed includes the signature of the constructor (the name and arguments), the constructor abbreviation, the exposure status of the constructor, and the name of the library source file for the constructor.

If operation information about a specific domain is wanted, the full or abbreviated domain name may be used. For example,

```
)show POLY INT
)show POLY INT )operations
)show Polynomial Integer
)show Polynomial Integer )operations
```

are among the combinations that will display the operations exported by the domain Polynomial(Integer) (as opposed to the general domain constructor Polynomial). Attributes may be listed by using the)attributes option.

Also See:

- o)display
- o)set
- o)what

)spool help page Command

48.1 spool help page man page

— spool.help —

```
=====
A.23. )spool
=====
```

User Level Required: interpreter

Command Syntax:

-)spool [fileName]
-)spool

Command Description:

This command is used to save (spool) all AXIOM input and output into a file, called a spool file. You can only have one spool file active at a time. To start spool, issue this command with a filename. For example,

```
)spool integrate.out
```

To stop spooling, issue)spool with no filename.

If the filename is qualified with a directory, then the output will be placed in that directory. If no directory information is given, the spool file will be placed in the current directory. The current directory is the directory from which you started AXIOM or is the directory you specified using the)cd command.

— synonym.help —

```
=====
A.24. )synonym
=====
```

User Level Required: interpreter

Command Syntax:

-)synonym
-)synonym synonym fullCommand
-)what synonyms

Command Description:

This command is used to create short synonyms for system command expressions. For example, the following synonyms might simplify commands you often use.

```
)synonym save      history )save
)synonym restore   history )restore
)synonym mail      system mail
)synonym ls        system ls
)synonym fortran   set output fortran
```

Once defined, synonyms can be used in place of the longer command expressions. Thus

```
)fortran on
```

is the same as the longer

```
)set fortran output on
```

To list all defined synonyms, issue either of

```
)synonyms
)what synonyms
```

To list, say, all synonyms that contain the substring ‘‘ap’’, issue

```
)what synonyms ap
```

Also See:

- o `)set`
- o `)what`

Chapter 51

)system help page Command

51.1 system help page man page

— system.help —

```
=====
A.25. )system
=====
```

User Level Required: interpreter

Command Syntax:

-)system cmdExpression

Command Description:

This command may be used to issue commands to the operating system while remaining in AXIOM. The cmdExpression is passed to the operating system for execution.

To get an operating system shell, issue, for example,)system sh. When you enter the key combination, Ctrl-D (pressing and holding the Ctrl key and then pressing the D key) the shell will terminate and you will return to AXIOM. We do not recommend this way of creating a shell because Lisp may field some interrupts instead of the shell. If possible, use a shell running in another window.

If you execute programs that misbehave you may not be able to return to AXIOM. If this happens, you may have no other choice than to restart AXIOM and restore the environment via)history)restore, if possible.

53.1 trace help page man page

— trace.help —

```
=====
A.26. )trace
=====
```

User Level Required: interpreter

Command Syntax:

-)trace
-)trace)off

-)trace function [options]
-)trace constructor [options]
-)trace domainOrPackage [options]

where options can be one or more of

-)after S-expression
-)before S-expression
-)break after
-)break before
-)cond S-expression
-)count
-)count n
-)depth n
-)local op1 [... opN]
-)nonquietly

```

- )nt
- )off
- )only listOfDataToDisplay
- )ops
- )ops op1 [... opN ]
- )restore
- )stats
- )stats reset
- )timer
- )varbreak
- )varbreak var1 [... varN ]
- )vars
- )vars var1 [... varN ]
- )within executingFunction

```

Command Description:

This command is used to trace the execution of functions that make up the AXIOM system, functions defined by users, and functions from the system library. Almost all options are available for each type of function but exceptions will be noted below.

To list all functions, constructors, domains and packages that are traced, simply issue

```
)trace
```

To untrace everything that is traced, issue

```
)trace )off
```

When a function is traced, the default system action is to display the arguments to the function and the return value when the function is exited. Note that if a function is left via an action such as a THROW, no return value will be displayed. Also, optimization of tail recursion may decrease the number of times a function is actually invoked and so may cause less trace information to be displayed. Other information can be displayed or collected when a function is traced and this is controlled by the various options. Most options will be of interest only to AXIOM system developers. If a domain or package is traced, the default action is to trace all functions exported.

Individual interpreter, lisp or boot functions can be traced by listing their names after)trace. Any options that are present must follow the functions to be traced.

```
)trace f
```

traces the function f. To untrace f, issue

```
)trace f )off
```

Note that if a function name contains a special character, it will be necessary to escape the character with an underscore

```
)trace _/D_,1
```

To trace all domains or packages that are or will be created from a particular constructor, give the constructor name or abbreviation after)trace.

```
)trace MATRIX
```

```
)trace List Integer
```

The first command traces all domains currently instantiated with Matrix. If additional domains are instantiated with this constructor (for example, if you have used Matrix(Integer) and Matrix(Float)), they will be automatically traced. The second command traces List(Integer). It is possible to trace individual functions in a domain or package. See the)ops option below.

The following are the general options for the)trace command.

```
)break after
```

causes a Lisp break loop to be entered after exiting the traced function.

```
)break before
```

causes a Lisp break loop to be entered before entering the traced function.

```
)break
```

is the same as)break before.

```
)count
```

causes the system to keep a count of the number of times the traced function is entered. The total can be displayed with)trace)stats and cleared with)trace)stats reset.

```
)count n
```

causes information about the traced function to be displayed for the first n executions. After the nth execution, the function is untraced.

```
)depth n
```

causes trace information to be shown for only n levels of recursion of the traced function. The command

```
)trace fib )depth 10
```

will cause the display of only 10 levels of trace information for the recursive execution of a user function fib.

)math
causes the function arguments and return value to be displayed in the AXIOM monospace two-dimensional math format.

)nonquietly
causes the display of additional messages when a function is traced.

)nt
This suppresses all normal trace information. This option is useful if the **)count** or **)timer** options are used and you are interested in the statistics but not the function calling information.

)off
causes untracing of all or specific functions. Without an argument, all functions, constructors, domains and packages are untraced. Otherwise, the given functions and other objects are untraced. To immediately retrace the untraced functions, issue **)trace** **)restore**.

)only listOfDataToDisplay
causes only specific trace information to be shown. The items are listed by using the following abbreviations:

a	display all arguments
v	display return value
1	display first argument
2	display second argument
15	display the 15th argument, and so on

)restore
causes the last untraced functions to be retraced. If additional options are present, they are added to those previously in effect.

)stats
causes the display of statistics collected by the use of the **)count** and **)timer** options.

)stats reset
resets to 0 the statistics collected by the use of the **)count** and **)timer** options.

)timer
causes the system to keep a count of execution times for the traced function. The total can be displayed with **)trace** **)stats** and cleared with **)trace** **)stats reset**.

)varbreak var1 [... varN]
causes a Lisp break loop to be entered after the assignment to any of the listed variables in the traced function.

)vars

causes the display of the value of any variable after it is assigned in the traced function. Note that library code must have been compiled (see description of command `)compile`) using the `)vartrace` option in order to support this option.

`)vars var1 [... varN]`

causes the display of the value of any of the specified variables after they are assigned in the traced function. Note that library code must have been compiled (see description of command `)compile`) using the `)vartrace` option in order to support this option.

`)within executingFunction`

causes the display of trace information only if the traced function is called when the given `executingFunction` is running.

The following are the options for tracing constructors, domains and packages.

`)local [op1 [... opN]]`

causes local functions of the constructor to be traced. Note that to untrace an individual local function, you must use the fully qualified internal name, using the escape character `_` before the semicolon.

`)trace FRAC)local`

`)trace FRAC_;cancelGcd)off`

`)ops op1 [... opN]`

By default, all operations from a domain or package are traced when the domain or package is traced. This option allows you to specify that only particular operations should be traced. The command

`)trace Integer)ops min max _+ _-`

traces four operations from the domain `Integer`. Since `+` and `-` are special characters, it is necessary to escape them with an underscore.

)undo help page Command

54.1 undo help page man page

— undo.help —

```
=====
A.27. )undo
=====
```

User Level Required: interpreter

Command Syntax:

-)undo
-)undo integer
-)undo integer [option]
-)undo)redo

where option is one of

-)after
-)before

Command Description:

This command is used to restore the state of the user environment to an earlier point in the interactive session. The argument of an)undo is an integer which must designate some step number in the interactive session.

```
)undo n
)undo n )after
```

These commands return the state of the interactive environment to that immediately after step *n*. If *n* is a positive number, then *n* refers to step number *n*. If *n* is a negative number, it refers to the *n*th previous command (that is, undoes the effects of the last *-n* commands).

A `)clear` all resets the `)undo` facility. Otherwise, an `)undo` undoes the effect of `)clear` with options `properties`, `value`, and `mode`, and that of a previous `undo`. If any such system commands are given between steps *n* and *n* + 1 (*n* > 0), their effect is undone for `)undo m` for any $0 < m \leq n$.

The command `)undo` is equivalent to `)undo -1` (it undoes the effect of the previous user expression). The command `)undo 0` undoes any of the above system commands issued since the last user expression.

`)undo n)before`

This command returns the state of the interactive environment to that immediately before step *n*. Any `)undo` or `)clear` system commands given before step *n* will not be undone.

`)undo)redo`

This command reads the file `redo.input`, created by the last `)undo` command. This file consists of all user input lines, excluding those backtracked over due to a previous `)undo`.

The command `)history)write` will eliminate the “undone” command lines of your program.

Also See:

o `)history`

1

54.2 Evaluation

Some Antique Comments About the Interpreter

EVAL BOOT contains the top level interface to the Scratchhpad-II interpreter. The Entry point into the interpreter from the parser is `processInteractive`.

The type analysis algorithm is contained in the file `BOTMUP BOOT`, and `MODSEL boot`, the map handling routines are in `MAP BOOT` and `NEWMAP BOOT`, and the interactive coerce routines are in `COERCE BOOT` and `COERCEFN BOOT`.

¹ “history” (35.4.7 p 580)

- **value:** Value properties are always triples. This is where the values of variables are stored. We also build value properties for internal nodes during the bottom up phase.
- **mode:** This is the declared type of an identifier.

There are several different environments used in the interpreter:

- **\$InteractiveFrame:** this is the environment where the user values are stored. Any side effects of evaluation of a top-level expression are stored in this environment. It is always used as the starting environment for interpretation.
- **\$e:** This is the name used for **\$InteractiveFrame** while interpreting.
- **\$env:** This is local environment used by the interpreter. Only temporary information (such as types of local variables) is stored in **\$env**. It is thrown away after evaluation of each expression.

Frequently used global variables:

- **\$genValue:** if true then evaluate generated code, otherwise leave code unevaluated. If **\$genValue** is false then we are compiling.
- **\$op:** name of the top level operator (unused except in map printing)
- **\$mapList:** list of maps being type analyzed, used in recursive map type analysis.
- **\$compilingMap:** true when compiling a map, used to detect where to THROW when interpret-only is invoked
- **\$compilingLoop:** true when compiling a loop body, used to control nesting level of interp-only loop CATCH points
- **\$interpOnly:** true when in interpret only mode, used to call alternate forms of COLLECT and REPEAT.
- **\$inCOLLECT:** true when compiling a COLLECT, used only for hacked stream compiler.
- **\$StreamFrame:** used in printing streams, it is the environment where local stream variables are stored
- **\$declaredMode:** Weak type propagation for symbols, set in upCOERCE and upLET. This variable is used to determine the alternate polynomial types of Symbols.
- **\$localVars:** list of local variables in a map body
- **\$MapArgumentTypeList:** hack for stream compilation

```

54.3 Data Structures

`$frameRecord = [delta1, delta2, ...]` where `delta(i)` contains changes in the “backwards” direction. Each `delta(i)` has the form `((var . proplist)...)` where `proplist` denotes an ordinary proplist. For example, an entry of the form `((x (value) (mode (Integer))))...` indicates that to undo 1 step, `x`’s value is cleared and its mode should be set to `(Integer)`.

A `delta(i)` of the form `(systemCommand . delta)` is a special delta indicating changes due to system commands executed between the last command and the current command. By recording these deltas separately, it is possible to undo to either BEFORE or AFTER the command. These special `delta(i)`s are given ONLY when a system command is given which alters the environment.

Note: `recordFrame('system)` is called before a command is executed, and `recordFrame('normal)` is called after (see `processInteractive1`). If no changes are found for former, no special entry is given.

The `$previousBindings` is a copy of the CAAR `$InteractiveFrame`. This is used to compute the `delta(i)s` stored in `$frameRecord`.

Chapter 55

)what help page Command

55.1 what help page man page

— what.help —

```
=====
A.28. )what
=====
```

User Level Required: interpreter

Command Syntax:

```
- )what categories pattern1 [pattern2 ...]
- )what commands  pattern1 [pattern2 ...]
- )what domains   pattern1 [pattern2 ...]
- )what operations pattern1 [pattern2 ...]
- )what packages  pattern1 [pattern2 ...]
- )what synonym   pattern1 [pattern2 ...]
- )what things    pattern1 [pattern2 ...]
- )apropos        pattern1 [pattern2 ...]
```

Command Description:

This command is used to display lists of things in the system. The patterns are all strings and, if present, restrict the contents of the lists. Only those items that contain one or more of the strings as substrings are displayed. For example,

```
)what synonym
```

displays all command synonyms,

)what synonym ver

displays all command synonyms containing the substring ‘ver’,

)what synonym ver pr

displays all command synonyms containing the substring ‘ver’ or the substring ‘pr’. Output similar to the following will be displayed

----- System Command Synonyms -----

user-defined synonyms satisfying patterns:

ver pr

```
)apr ..... )what things
)apropos ..... )what things
)prompt ..... )set message prompt
)version ..... )lisp *yearweek*
```

Several other things can be listed with the)what command:

categories displays a list of category constructors.

commands displays a list of system commands available at your user-level. Your user-level is set via the)set userlevel command. To get a description of a particular command, such as ‘)what’, issue)help what.

domains displays a list of domain constructors.

operations displays a list of operations in the system library.

It is recommended that you qualify this command with one or more patterns, as there are thousands of operations available. For example, say you are looking for functions that involve computation of eigenvalues. To find their names, try)what operations eig. A rather large list of operations is loaded into the workspace when this command is first issued. This list will be deleted when you clear the workspace via)clear all or)clear completely. It will be re-created if it is needed again.

packages displays a list of package constructors.

synonym lists system command synonyms.

things displays all of the above types for items containing the pattern strings as substrings. The command synonym)apropos is equivalent to)what things.

Also See:

- o)display
- o)set
- o)show

Chapter 59

Handlers for Special Forms

This file contains the functions which do type analysis and evaluation of special functions in the interpreter. Special functions are ones which are not defined in the algebra code, such as assignment, construct, COLLECT and declaration.

Operators which require special handlers all have a LISP “up” property which is the name of the special handler, which is always the word “up” followed by the operator name. If an operator has this “up” property the handler is called automatically from bottomUp instead of general modemap selection.

The up handlers are usually split into two pieces, the first is the up function itself, which performs the type analysis, and an “eval” function, which generates (and executes, if required) the code for the function.

The up functions always take a single argument, which is the entire attributed tree for the operation, and return the modeSet of the node, which is a singleton list containing the type computed for the node.

The eval functions can take any arguments deemed necessary. Actual evaluation is done if `$genValue` is true, otherwise code is generated.

(See the function analyzeMap for other things that may affect what is generated in these functions.)

These functions are required to do two things:

1. do a putValue on the operator vector with the computed value of the node, which is a triple. This is usually done in the eval functions.
2. do a putModeSet on the operator vector with a list of the computed type of the node. This is usually done in the up functions.

There are several special modes used in these functions:

1. Void is the mode that should be used for all statements that do not otherwise return values, such as declarations, loops, IF-THEN's without ELSE's, etc..

2. `$NoValueMode` and `$ThrowAwayMode` used to be used in situations where `Void` is now used, and are being phased out completely.

Chapter 65

Axiom Build-time Functions

65.0.24 defun spad-save

The **spad-save** function is just a cover function for more lisp system specific save functions. There is no standard name for saving a lisp image so we make one and conditionalize it at compile time.

This function is passed the name of an image that will be saved. The saved image contains all of the loaded functions.

This is used in the `src/interp/Makefile.pamphlet` in three places:

- creating `depsys`, an image for compiling axiom.

Some of the Common Lisp code we compile uses macros which are assumed to be available at compile time. The **DEPSYS** image is created to contain the compile time environment and saved. We pipe compile commands into this environment to compile from Common Lisp to machine dependent code.

```
DEPSYS=${OBJ}/${SYS}/bin/depsys
```

- creating `savesys`, an image for running axiom.

Once we've compile all of the Common Lisp files we fire up a clean lisp image called **LOADSYS**, load all of the final executable code and save it out as **SAVESYS**. The **SAVESYS** image is copied to the `${MNT}/${SYS}/bin` subdirectory and becomes the axiom executable image.

```
LOADSYS= ${OBJ}/${SYS}/bin/lisp
SAVESYS= ${OBJ}/${SYS}/bin/interpsys
AXIOMSYS= ${MNT}/${SYS}/bin/AXIOMsys
```

- creating `debugsys`, an image with all interpreted functions loaded.

Occasionally we need to really get into the system internals. The best way to do this is to run almost all of the lisp code interpreted rather than compiled (note that `cfuncs.lisp` and `sockio.lisp` still need to be loaded in compiled form as they depend on the loader to link with lisp internals). This image is nothing more than a load of the file `src/interp/debugsys.lisp.pamphlet`. If you need to make test modifications you can add code to that file and it will show up here.

```
DEBUGSYS=${OBJ}/${SYS}/bin/debugsys
```

```
[save-system p??]
[$SpadServer p12]
[$openServerIfTrue p10]
```

— defun spad-save —

```
(defun user::spad-save (save-file)
  (declare (special |$SpadServer| $openServerIfTrue))
  (setq |$SpadServer| nil)
  (setq $openServerIfTrue t)
  #+:AKCL
  (system::save-system save-file)
  #+:allegro
  (if (fboundp 'boot::restart)
      (excl::dumplisp :name save-file :restart-function #'boot::restart)
      (excl::dumplisp :name save-file))
  #+:Lucid
  (if (fboundp 'boot::restart)
      (sys::disksave save-file :restart-function #'boot::restart)
      (sys::disksave save-file))
  #+:CCL
  (preserve)
)
```

Chapter 66

Exposure Groups

Exposure groups are a way of controlling the namespace available to the user. Certain algebra files are only useful for internal purposes but they contain functions have common names (like “map”. In order to separate the user visible functions from the internal functions the algebra files are collected into “exposure groups”. These large groups are grouped into sets in the variable `$globalExposureGroupAlist`.

Exposure group information is kept in the local frame. For more information “The Frame Mechanism” 33.3.1 on page 550.

Chapter 67

Databases

67.1 Database structure

In order to understand this program you need to understand some details of the structure of the databases it reads. Axiom has 5 databases, the `interp.daase`, `operation.daase`, `category.daase`, `compress.daase`, and `browse.daase`. The `compress.daase` is special and does not follow the normal database format.

67.1.1 kaf File Format

This documentation refers to kaf files which are random access files. `nrllib` files are kaf files (look for `nrllib/index.kaf`) The format of a random access file is

```
byte-offset-of-key-table
first-entry
second-entry
...
last-entry
((key1 . first-entry-byte-address)
 (key2 . second-entry-byte-address)
 ...
 (keyN . last-entry-byte-address))
```

The key table is a standard lisp alist.

To open a database you fetch the first number, seek to that location, and `(read)` which returns the key-data alist. To look up data you index into the key-data alist, find the `ith-entry-byte-address`, seek to that address, and `(read)`.

For instance, see `src/share/algebra/users.daase/index.kaf`

One existing optimization is that if the data is a simple thing like a symbol then the `nth-entry-byte-address` is replaced by immediate data.

Another existing one is a compression algorithm applied to the data so that the very long names don't take up so much space. We could probably remove the compression algorithm as 64k is no longer considered 'huge'. The database-abbreviation routine handles this on read and write-compress handles this on write. The squeeze routine is used to compress the keys, the unsqueeze routine uncompresses them. Making these two routines disappear should remove all of the compression.

Indeed, a faster optimization is to simply read the whole database into the image before it is saved. The system would be easier to understand and the interpreter would be faster.

The fastest optimization is to fix the time stamp mechanism which is currently broken. Making this work requires a small bit of coordination at 'make' time which I forgot to implement.

67.1.2 Database Files

Database files are very similar to kaf files except that there is an optimization (currently broken) which makes the first item a pair of two numbers. The first number in the pair is the offset of the key-value table, the second is a time stamp. If the time stamp in the database matches the time stamp in the image the database is not needed (since the internal hash tables already contain all of the information). When the database is built the time stamp is saved in both the gcl image and the database.

Regarding the 'ancestors field for a category: At database build time there exists a `*ancestors-hash*` hash table that gets filled with CATEGORY (not domain) ancestor information. This later provides the information that goes into `interp.daase`. This `*ancestors-hash*` does not exist at normal runtime (it can be made by a call to `genCategoryTable`). Note that the ancestor information in `*ancestors-hash*` (and hence `interp.daase`) involves #1, #2, etc instead of R, Coef, etc. The latter thingies appear in all `.nrlib/index.kaf` files. So we need to be careful when we `)lib` categories and update the ancestor info.

This file contains the code to build, open and access the `.daase` files. This file contains the code to `)library` `nrlibs` and `asy` files

There is a major issue about the data that resides in these databases. the fundamental problem is that the system requires more information to build the databases than it needs to run the interpreter. in particular, `modemap.daase` is constructed using properties like "modemaps" but the interpreter will never ask for this information.

So, the design is as follows:

- the `modemap.daase` needs to be built. this is done by doing a `)library` on ALL of the `nrlib` files that are going into the system. this will bring in "modemap" information and add it to the `*modemaps-hash*` hashtable.
- database build proceeds, accessing the "modemap" property from the hashtables. once this completes this information is never used again.
- the `interp.daase` database is built. this contains only the information necessary to run the interpreter. note that during the running of the interpreter users can extend the

system by do a)library on a new nrlib file. this will cause fields such as "modemap" to be read and hashed.

Each constructor (e.g. LIST) had one library directory (e.g. LIST.nrlib). This directory contained a random access file called the index.kaf file. These files contain runtime information such as the operationAlist and the ConstructorModemap. At system build time we merge all of these .nrlib/index.kaf files into one database, INTERP.daase. Requests to get information from this database are cached so that multiple references do not cause additional disk i/o.

This database is left open at all times as it is used frequently by the interpreter. one minor complication is that newly compiled files need to override information that exists in this database.

The design calls for constructing a random read (kaf format) file that is accessed by functions that cache their results. when the database is opened the list of constructor-index pairs is hashed by constructor name. a request for information about a constructor causes the information to replace the index in the hash table. since the index is a number and the data is a non-numeric sexpr there is no source of confusion about when the data needs to be read.

The format of this new database is as follows:

```
first entry:
  an integer giving the byte offset to the constructor alist
  at the bottom of the file
second and subsequent entries (one per constructor)
  (operationAlist)
  (constructorModemap)
  ....
last entry: (pointed at by the first entry)
  an alist of (constructor . index) e.g.
    ( (PI offset-of-operationAlist offset-of-constructorModemap)
      (NMI offset-of-operationAlist offset-of-constructorModemap)
      ....)
This list is read at open time and hashed by the car of each item.
```

The system has been changed to use the property list of the symbols rather than hash tables. since we already hashed once to get the symbol we need only an offset to get the property list. this also has the advantage that eq hash tables no longer need to be moved during garbage collection.

There are 3 potential speedups that could be done.

- the best would be to use the value cell of the symbol rather than the property list but i'm unable to determine all uses of the value cell at the present time.
- a second speedup is to guarantee that the property list is a single item, namely the database structure. this removes an assoc but leaves one open to breaking the system if someone adds something to the property list. this was not done because of the danger mentioned.

- a third speedup is to make the `getdatabase` call go away, either by making it a macro or eliding it entirely. this was not done because we want to keep the flexibility of changing the database forms.

The new design does not use hash tables. the database structure contains an entry for each item that used to be in a hash table. initially the structure contains file-position pointers and these are replaced by real data when they are first looked up. the database structure is kept on the property list of the constructor, thus, `(get '—DenavitHartenbergMatrix— 'database)` will return the database structure object.

Each operation has a property on its symbol name called `'operation` which is a list of all of the signatures of operations with that name.

67.1.3 `defstruct $database`

— initvars —

```
(defstruct database
  abbreviation      ; interp.
  ancestors         ; interp.
  constructor       ; interp.
  constructorcategory ; interp.
  constructorkind   ; interp.

  cosig            ; interp.
  defaultdomain    ; interp.
  modemaps         ; interp.
  niladic          ; interp.
  object           ; interp.
  operationalist    ; interp.
  documentation    ; browse.
  constructorform   ; browse.
  attributes       ; browse.
  predicates       ; browse.
  sourcefile       ; browse.
  parents          ; browse.
  users            ; browse.
  dependents       ; browse.
  spare            ; superstition
) ; database structure
```

67.1.4 defvar **defaultdomain-list**

There are only a small number of domains that have default domains. rather than keep this slot in every domain we maintain a list here.

— **initvars** —

```
(defvar *defaultdomain-list* '(
  (|MultisetAggregate| |Multiset|)
  (|FunctionSpace| |Expression|)
  (|AlgebraicallyClosedFunctionSpace| |Expression|)
  (|ThreeSpaceCategory| |ThreeSpace|)
  (|DequeAggregate| |Deque|)
  (|ComplexCategory| |Complex|)
  (|LazyStreamAggregate| |Stream|)
  (|AssociationListAggregate| |AssociationList|)
  (|QuaternionCategory| |Quaternion|)
  (|PriorityQueueAggregate| |Heap|)
  (|PointCategory| |Point|)
  (|PlottableSpaceCurveCategory| |Plot3D|)
  (|PermutationCategory| |Permutation|)
  (|StringCategory| |String|)
  (|FileNameCategory| |FileName|)
  (|OctonionCategory| |Octonion|)))
```

—————

67.1.5 defvar **operation-hash**

— **initvars** —

```
(defvar *operation-hash* nil "given an operation name, what are its modemaps?")
```

—————

67.1.6 defvar **hasCategory-hash**

This hash table is used to answer the question “does domain x have category y?”. this is answered by constructing a pair of (x . y) and doing an equal hash into this table.

— **initvars** —

```
(defvar *hasCategory-hash* nil "answers x has y category questions")
```

—————

67.1.7 defvar \$*miss*

This variable is used for debugging. If a hash table lookup fails and this variable is non-nil then a message is printed.

— initvars —

```
(defvar *miss* nil "print out cache misses on getdatabase calls")
```

Note that constructorcategory information need only be kept for items of type category. this will be fixed in the next iteration when the need for the various caches are reviewed

Note that the *modemaps-hash* information does not need to be kept for system files. these are precomputed and kept in modemap.daase however, for user-defined files these are needed. Currently these are added to the database for 2 reasons; there is a still-unresolved issue of user database extensions and this information is used during database build time

67.1.8 Database streams

This are the streams for the databases. They are always open. There is an optimization for speeding up system startup. If the database is opened and the ..stream-stamp* variable matches the position information in the database then the database is NOT read in and is assumed to match the in-core version

67.1.9 defvar \$*compressvector*

This is an initialization function for the constructor database it sets up 2 hash tables, opens the database and hashes the index values.

There is a slight asymmetry in this code. The sourcefile information for system files is only the filename and extension. For user files it contains the full pathname. when the database is first opened the sourcefile slot contains system names. The lookup function has to prefix the “\$spadroot” information if the directory-namestring is null (we don’t know the real root at database build time).

An object-hash table is set up to look up nrlib and ao information. this slot is empty until a user does a)library call. We remember the location of the nrlib or ao file for the users local library at that time. A NIL result from this probe means that the library is in the system-specified place. When we get into multiple library locations this will also contain system files.

```

67.1.38 defun Make new databases

Making new databases consists of:

1. reset all of the system hash tables
2. set up Union, Record and Mapping
3. map)library across all of the system files (fills the databases)
4. loading some normally autoloaded files
5. making some database entries that are computed (like ancestors)
6. writing out the databases
7. write out 'warm' data to be loaded into the image at build time

Note that this process should be done in a clean image followed by a rebuild of the system image to include the new index pointers (e.g. *interp-stream-stamp*)

The system will work without a rebuild but it needs to re-read the databases on startup. Rebuilding the system will cache the information into the image and the databases are opened

but not read, saving considerable startup time. Also note that the order the databases are written out is critical. The `interp.daase` depends on prior computations and has to be written out last.

The `build-name-to-pamphlet-hash` builds a hash table whose key-`λ`value is:

- abbreviation -`λ` pamphlet file name
- abbreviation-line -`λ` pamphlet file position
- constructor -`λ` pamphlet file name
- constructor-line -`λ` pamphlet file position

is the symbol of the constructor name and whose value is the name of the source file without any path information. We hash the constructor abbreviation to pamphlet file name. [local-database p1013]

67.1.42 compress.daase

The compress database is special. It contains a list of symbols. The character string name of a symbol in the other databases is represented by a negative number. To get the real symbol back you take the absolute value of the number and use it as a byte index into the compress database. In this way long symbol names become short negative numbers.

67.1.50 Building the browse.daase from hash tables

```
format of an entry in browse.daase:
( constructorname
  sourcefile
  constructorform
  documentation
  attributes
  predicates
)
```

This is essentially the same overall process as write-interpdb.

We reserve some space for the (key-table-byte-position . timestamp)

We loop across the list of constructors dumping the data and remembering the byte positions in a key-value pair table.

We dump the final key-value pair table, write the byte position and time stamp at the top of the file and close the file.

Special Lisp Functions

69.1 Axiom control structure macros

Axiom used various control structures in the boot code which are not available in Common Lisp. We write some macros here to make the boot to lisp translations easier to read.

69.1.1 defun put

— defun put —

```
(defun put (sym ind val) (setf (get sym ind) val))
```

—————

69.1.2 defmacro while

While the condition is true, repeat the body. When the condition is false, return t.

— defmacro while —

```
(defmacro while (condition &rest body)
  '(loop (if (not ,condition) (return t)) ,@body))
```

—————

69.1.3 defmacro whileWithResult

While the condition is true, repeat the body. When the condition is false, return the result form's value.

— defmacro whileWithResult —

```
(defmacro whileWithResult (condition result &rest body)
  '(loop (if (not ,condition) ,@result) ,@body))
```

—————

69.2 Filename Handling

This code implements the Common Lisp pathname functions for Lisp/VM. On VM, a filename is 3-list consisting of the filename, filetype and filemode. We also UPCASE everything.

69.2.1 defun namestring

Chapter 71

Common Lisp Algebra Support

These functions are called directly from the algebra source code. They fall into two basic categories, one are the functions that are raw Common Lisp calls and the other are Axiom specific functions or macros.

Raw function calls are used where there is an alignment of the Axiom type and the underlying representation in Common Lisp. These form the support pillars upon which Axiom rests. For instance, the 'EQ' function is called to support the Axiom equivalent 'eq?' function.

Macros are used to add type information in order to make low level operations faster. An example is the use of macros in DoubleFloat to add Common Lisp type information. Since DoubleFloat is machine arithmetic we give the compiler explicit type information so it can generate fast code.

Functions are used to do manipulations which are Common Lisp operations but the Axiom semantics are not the same. Because Axiom was originally written in Maclisp, then VMLisp, and then Common Lisp some of these old semantics survive.

71.1 InputForm

71.1.1 defun unparseInputForm

This fixes bug 7217. The default title generation is bogus. This is called from the unparse function in InputForm, bookvol10.3 Given a form, u , we try to recover the input line that created it. [InteractiveMode p24]

[formatSigAsTeX p??]

71.14 Plot3d

We catch numeric errors and throw a different failure than normal. The `trapNumericErrors` macro will return a pair of the the form `Union(type-of-form, "failed")`. This pair is tested for eq-ness so it has to be unique. It lives in the defvar `$numericFailure`. The old value of the `$BreakMode` variable is saved in a defvar named `$oldBreakMode`.

71.14.1 defvar \$numericFailure

This is a failed union branch which is the value returned for numeric failure.

— initvars —

```
(defvar |$numericFailure| (cons 1 "failed"))
```

71.14.2 defvar \$oldBreakMode

— initvars —

```
(defvar |$oldBreakMode| nil "the old value of the $BreakMode variable")
```

71.14.3 defmacro trapNumericErrors

The following macro evaluates form returning Union(type-of form, "failed"). It is used in the myTrap local function in Plot3d.

— defmacro trapNumericErrors —

```
(defmacro |trapNumericErrors| (form)
  '(let ((|$oldBreakMode| |$BreakMode|) (|$BreakMode| '|trapNumerics|) (val))
    (declare (special |$BreakMode| |$numericFailure| |$oldBreakMode|))
    (setq val (catch '|trapNumerics| ,form))
    (if (eq val |$numericFailure|) val (cons 0 val))))
```

71.15 DoubleFloatVector

Double Float Vectors are simple arrays of lisp double-floats made available at the Spad language level. Note that these vectors are 0 based whereas other Spad language vectors are 1-based.

71.15.1 defmacro dlen

DoubleFloatVector Qsize function support

— defmacro dlen —

```
(defmacro dlen (v)
  '(length (the (simple-array double-float (*)) ,v)))
```

71.15.2 defmacro make-double-vector

DoubleFloatVector Qnew function support

— **defmacro make-double-vector** —

```
(defmacro make-double-vector (n)
  '(make-array (list ,n) :element-type 'double-float))
```

71.15.3 defmacro make-double-vector1

71.19 Integer

71.19.1 defun Integer divide function support

Note that this is defined as a SPADReplace function in Integer so that algebra code that uses the Integer divide function actually inlines a call to this code. The Integer domain contains the line:

```
(PUT (QUOTE |INT;divide;2$R;44|) (QUOTE |SPADreplace|) (QUOTE DIVIDE2))
```

— **defun divide2 0** —

```
(defun divide2 (x y)
  (multiple-value-call #'cons (truncate x y)))
```

71.19.2 defun Integer quo function support

Note that this is defined as a SPADReplace function in Integer so that algebra code that uses the Integer quo function actually inlines a call to this code. The Integer domain contains the line:

```
(PUT (QUOTE |INT;rem;3$;46|) (QUOTE |SPADreplace|) (QUOTE REMAINDER2))
```

Because these are identical except for name we make the symbol-functions equivalent. This was done in the original code for efficiency.

— defun remainder2 0 —

```
(setf (symbol-function 'remainder2) #'rem)
```

71.19.3 defun Integer quo function support

Note that this is defined as a SPADReplace function in Integer so that algebra code that uses the Integer quo function actually inlines a call to this code. The Integer domain contains the line:

```
(PUT (QUOTE |INT;quo;3$;45|) (QUOTE |SPADreplace|) (QUOTE QUOTIENT2))
```

— defun quotient2 0 —

```
(defun quotient2 (x y)
  (values (truncate x y)))
```

71.19.4 defun Integer random function support

This is used for calls to random with no arguments. If an argument is supplied to random then the common lisp random function is called directly. This could be lifted up into the spad code.

— defun random 0 —

```
(defun |random| () (random (expt 2 26)))
```

71.20 IndexCard

71.20.1 defun IndexCard origin function support

```
[dbPart p??]  
[charPosition p??]  
[substring p??]

```

71.24 DoubleFloat

These macros wrap their arguments with strong type information in order to optimize doublefloat computations. They are used directly in the DoubleFloat domain (see Volume 10.3).

71.24.1 defmacro DFLessThan

Compute a strongly typed doublefloat comparison See Steele Common Lisp 1990 p293

— defmacro DFLessThan —

```
(defmacro DFLessThan (x y)
  '(< (the double-float ,x) (the double-float ,y)))
```

71.24.2 defmacro DFUnaryMinus

Compute a strongly typed unary doublefloat minus See Steele Common Lisp 1990 p295

— **defmacro DFUnaryMinus** —

```
(defmacro DFUnaryMinus (x)
  '(the double-float (- (the double-float ,x))))
```

—————

71.24.3 defmacro DFMinusp

Compute a strongly typed unary doublefloat test for negative See Steele Common Lisp 1990 p292

— **defmacro DFMinusp** —

```
(defmacro DFMinusp (x)
  '(minusp (the double-float ,x)))
```

—————

71.24.4 defmacro DFZerop

Compute a strongly typed unary doublefloat test for zero See Steele Common Lisp 1990 p292

— **defmacro DFZerop** —

```
(defmacro DFZerop (x)
  '(zerop (the double-float ,x)))
```

—————

71.24.5 defmacro DFAdd

Compute a strongly typed doublefloat addition See Steele Common Lisp 1990 p295

— **defmacro DFAdd** —

```
(defmacro DFAdd (x y)
  '(the double-float (+ (the double-float ,x) (the double-float ,y))))
```

—————

71.24.6 defmacro DFSubtract

Compute a strongly typed doublefloat subtraction See Steele Common Lisp 1990 p295

— **defmacro DFSubtract** —

```
(defmacro DFSubtract (x y)
  '(the double-float (- (the double-float ,x) (the double-float ,y))))
```

—————

71.24.7 defmacro DFMultiply

Compute a strongly typed doublefloat multiplication See Steele Common Lisp 1990 p296

— **defmacro DFMultiply** —

```
(defmacro DFMultiply (x y)
  '(the double-float (* (the double-float ,x) (the double-float ,y))))
```

—————

71.24.8 defmacro DFIntegerMultiply

Compute a strongly typed doublefloat multiplication by an integer. See Steele Common Lisp 1990 p296

— **defmacro DFIntegerMultiply** —

```
(defmacro DFIntegerMultiply (i y)
  '(the double-float (* (the integer ,i) (the double-float ,y))))
```

—————

71.24.9 defmacro DFMax

Choose the maximum of two doublefloats. See Steele Common Lisp 1990 p294

— **defmacro DFMax** —

```
(defmacro DFMax (x y)
  '(the double-float (max (the double-float ,x) (the double-float ,y))))
```

—————

71.24.10 defmacro DFMin

Choose the minimum of two doublefloats. See Steele Common Lisp 1990 p294

— **defmacro DFMin** —

```
(defmacro DFMin (x y)
  '(the double-float (min (the double-float ,x) (the double-float ,y))))
```

71.24.11 defmacro DFEq

Compare two doublefloats for equality, where equality is eq, or numbers of the same type with the same value. See Steele Common Lisp 1990 p105

— **defmacro DFEq** —

```
(defmacro DFEq (x y)
  '(eq (the double-float ,x) (the double-float ,y)))
```

71.24.12 defmacro DFDivide

Divide a doublefloat by a doublefloat See Steele Common Lisp 1990 p296

— **defmacro DFDivide** —

```
(defmacro DFDivide (x y)
  '(the double-float (/ (the double-float ,x) (the double-float ,y))))
```

71.24.13 defmacro DFIntegerDivide

Divide a doublefloat by an integer See Steele Common Lisp 1990 p296

— **defmacro DFIntegerDivide** —

```
(defmacro DFIntegerDivide (x i)
  '(the double-float (/ (the double-float ,x) (the integer ,i))))
```

71.24.14 defmacro DFSqrt

Compute the doublefloat square root of x . The result will be complex if the argument is negative. See Steele Common Lisp 1990 p302

— **defmacro DFSqrt** —

```
(defmacro DFSqrt (x)
  '(sqrt (the double-float ,x)))
```

71.24.15 defmacro DFLogE

Compute the doublefloat log of x with the base e . The result will be complex if the argument is negative. See Steele Common Lisp 1990 p301

— **defmacro DFLogE** —

```
(defmacro DFLogE (x)
  '(log (the double-float ,x)))
```

71.24.16 defmacro DFLog

Compute the doublefloat log of x with a given base b . The result will be complex if x is negative. See Steele Common Lisp 1990 p301

— **defmacro DFLog** —

```
(defmacro DFLog (x b)
  '(log (the double-float ,x) (the fixnum ,b)))
```

71.24.17 defmacro DFIntegerExpt

Compute the doublefloat expt of x with a given integer power i See Steele Common Lisp 1990 p300

— **defmacro DFIntegerExpt** —

```
(defmacro DFIntegerExpt (x i)
  '(the double-float (expt (the double-float ,x) (the integer ,i))))
```

71.24.18 defmacro DFExpt

Compute the doublefloat expt of x with a given power p . The result could be complex if the base is negative and the power is not an integer. See Steele Common Lisp 1990 p300

— **defmacro DFExpt** —

```
(defmacro DFExpt (x p)
  '(expt (the double-float ,x) (the double-float ,p)))
```

—————

71.24.19 defmacro DFExp

Compute the doublefloat exp with power e See Steele Common Lisp 1990 p300

— **defmacro DFExp** —

```
(defmacro DFExp (x)
  '(the double-float (exp (the double-float ,x))))
```

—————

71.24.20 defmacro DFSin

Compute a strongly typed doublefloat sin See Steele Common Lisp 1990 p304

— **defmacro DFSin** —

```
(defmacro DFSin (x)
  '(the double-float (sin (the double-float ,x))))
```

—————

71.24.21 defmacro DFCos

Compute a strongly typed doublefloat cos See Steele Common Lisp 1990 p304

— **defmacro DFCos** —

```
(defmacro DFCos (x)
  '(the double-float (cos (the double-float ,x))))
```

—————

71.24.22 defmacro DFTan

Compute a strongly typed doublefloat tan See Steele Common Lisp 1990 p304

— **defmacro DFTan** —

```
(defmacro DFTan (x)
  '(the double-float (tan (the double-float ,x))))
```

71.24.23 defmacro DFAsin

Compute a strongly typed doublefloat asin. The result is complex if the absolute value of the argument is greater than 1. See Steele Common Lisp 1990 p305

— **defmacro DFAsin** —

```
(defmacro DFAsin (x)
  '(asin (the double-float ,x)))
```

71.24.24 defmacro DFAcos

Compute a strongly typed doublefloat acos. The result is complex if the absolute value of the argument is greater than 1. See Steele Common Lisp 1990 p305

— **defmacro DFAcos** —

```
(defmacro DFAcos (x)
  '(acos (the double-float ,x)))
```

71.24.25 defmacro DFAtan

Compute a strongly typed doublefloat atan See Steele Common Lisp 1990 p305

— **defmacro DFAtan** —

```
(defmacro DFAtan (x)
  '(the double-float (atan (the double-float ,x))))
```

71.24.26 defmacro DFAtan2

Compute a strongly typed doublefloat atan with 2 arguments

$y = 0$	$x > 0$	Positive x-axis	0
$y > 0$	$x > 0$	Quadrant I	$0 < \text{result} < \pi/2$
$y > 0$	$x = 0$	Positive y-axis	$\pi/2$
$y > 0$	$x < 0$	Quadrant II	$\pi/2 < \text{result} < \pi$
$y = 0$	$x < 0$	Negative x-axis	π
$y < 0$	$x < 0$	Quadrant III	$-\pi < \text{result} < -\pi/2$
$y < 0$	$x = 0$	Negative y-axis	$-\pi/2$
$y < 0$	$x > 0$	Quadrant IV	$-\pi/2 < \text{result} < 0$
$y = 0$	$x = 0$	Origin	error

See Steele Common Lisp 1990 p306

— **defmacro DFAtan2** —

```
(defmacro DFAtan2 (y x)
  '(the double-float (atan (the double-float ,x) (the double-float ,y))))
```

—————

71.24.27 defmacro DFSinh

Compute a strongly typed doublefloat sinh

$$(e^z - e^{-z})/2$$

See Steele Common Lisp 1990 p308

— **defmacro DFSinh** —

```
(defmacro DFSinh (x)
  '(the double-float (sinh (the double-float ,x))))
```

—————

71.24.28 defmacro DFCosh

Compute a strongly typed doublefloat cosh

$$(e^z + e^{-z})/2$$

See Steele Common Lisp 1990 p308

— **defmacro DFCosh** —

```
(defmacro DFCosh (x)
  '(the double-float (cosh (the double-float ,x))))
```

71.24.29 defmacro DFTanh

Compute a strongly typed doublefloat tanh

$$(e^z - e^{-z}) / (e^z + e^{-z})$$

See Steele Common Lisp 1990 p308

— **defmacro DFTanh** —

```
(defmacro DFTanh (x)
  '(the double-float (tanh (the double-float ,x))))
```

71.24.30 defmacro DFAsinh

Compute the inverse hyperbolic sin.

$$\log \left(z + \sqrt{1 + z^2} \right)$$

See Steele Common Lisp 1990 p308

— **defmacro DFAsinh** —

```
(defmacro DFAsinh (x)
  '(the double-float (asinh (the double-float ,x))))
```

71.24.31 defmacro DFAcosh

Compute the inverse hyperbolic cos. Note that the acosh function will return a complex result if the argument is less than 1.

$$\log \left(z + (z + 1) \sqrt{(z - 1) / (z + 1)} \right)$$

See Steele Common Lisp 1990 p308

— **defmacro DFAcosh** —

```
(defmacro DFAcosh (x)
  '(acosh (the double-float ,x)))
```

71.24.32 defmacro DFAtanh

Compute the inverse hyperbolic tan. Note that the acosh function will return a complex result if the argument is greater than 1.

$$\log \left((1+z) \sqrt{1/(1-z^2)} \right)$$

See Steele Common Lisp 1990 p308

— **defmacro DFAtanh** —

```
(defmacro DFAtanh (x)
  '(atanh (the double-float ,x)))
```

71.24.33 defun Machine specific float numerator

This is used in the DoubleFloat integerDecode function

— **defun integer-decode-float-numerator 0** —

```
(defun integer-decode-float-numerator (x)
  (integer-decode-float x))
```

71.24.34 defun Machine specific float denominator

This is used in the DoubleFloat integerDecode function

— **defun integer-decode-float-denominator 0** —

```
(defun integer-decode-float-denominator (x)
  (multiple-value-bind (mantissa exponent sign) (integer-decode-float x)
    (declare (ignore mantissa sign)) (expt 2 (abs exponent)))))
```

71.24.35 defun Machine specific float sign

This is used in the DoubleFloat integerDecode function

— **defun integer-decode-float-sign 0** —

```
(defun integer-decode-float-sign (x)
  (multiple-value-bind (mantissa exponent sign) (integer-decode-float x)
    (declare (ignore mantissa exponent)) sign))
```

71.24.36 defun Machine specific float bit length

This is used in the DoubleFloat integerDecode function

— **defun integer-decode-float-exponent 0** —

```
(defun integer-decode-float-exponent (x)
  (multiple-value-bind (mantissa exponent sign) (integer-decode-float x)
    (declare (ignore mantissa sign)) exponent))
```

71.24.37 defun Decode floating-point values

This function is used by DoubleFloat to implement the “mantissa” and “exponent” functions.

— **defun manexp 0** —

```
(defun manexp (u)
  (multiple-value-bind (f e s)
    (decode-float u)
    (cons (* s f) e)))
```

71.24.38 defun The cotangent routine

The cotangent function is defined as

$$\cot(z) = \frac{1}{\tan(z)}$$

— **defun cot 0** —

```
(defun cot (a)
  (if (or (> a 1000.0) (< a -1000.0))
      (/ (cos a) (sin a))
      (/ 1.0 (tan a))))
```

71.24.39 defun The inverse cotangent function

The inverse cotangent (arc-cotangent) function is defined as

$$acot(z) = cot^{-1}(z) = tan^{-1}\left(\frac{1}{z}\right)$$

See Steele Common Lisp 1990 pp305-307

— defun acot 0 —

```
(defun acot (a)
  (if (> a 0.0)
      (if (> a 1.0)
          (atan (/ 1.0 a))
          (- (/ pi 2.0) (atan a)))
      (if (< a -1.0)
          (- pi (atan (/ -1.0 a)))
          (+ (/ pi 2.0) (atan (- a))))))

Chapter 72

OpenMath

72.1 A Technical Overview[4]

OpenMath is a standard for representing mathematical data in as unambiguous a way as possible. It can be used to exchange mathematical objects between software packages or via email, or as a persistent data format in a database. It is tightly focussed on representing semantic information and is not intended to be used directly for presentation, although tools exist to facilitate this.

The original motivation for OpenMath came from the Computer Algebra community. Computer Algebra packages were getting bigger and more unwieldy, and it seemed reasonable to adopt a generic "plug and play" architecture to allow specialised programs to be used from general purpose environments. There were plenty of mechanisms for connecting software components together, but no common format for representing the underlying data objects. It quickly became clear that any standard had to be vendor-neutral and that objects encoded in OpenMath should not be too verbose. This has led to the design outlined below.

In 1998, the Worldwide Web Consortium (W3C) produced its first recommendation for the Extensible Markup Language (XML), intended to be a universal format for representing structured information on the worldwide web. It was swiftly followed by the first MathML recommendation which is an XML application oriented mainly towards the presentation (i.e. the rendering) of mathematical expressions.

The formal definition of OpenMath is contained within The OpenMath Standard and its accompanying documents, and the reader is referred there for more details.

72.1.1 The OpenMath Architecture

The OpenMath representation of a mathematical structure is referred to as an OpenMath object. This is an abstract structure which is represented concretely via an OpenMath encoding. These encoded objects are what an OpenMath application would read and write,

and in practice the OpenMath objects themselves almost never exist, except on paper. The advantage of this is that OpenMath is not tied to any one underlying mechanism: in the past we have used functional, SGML and binary encodings. The current favourite is XML, as described below, and we will tend to use XML notation when describing OpenMath objects (even though strictly speaking the XML representation is an encoding). OpenMath Objects

Formally, an OpenMath object is a labelled tree whose leaves are the basic OpenMath objects integers, IEEE double precision floats, unicode strings, byte arrays, variables or symbols. Of these, symbols are the most interesting since they consist of a name and a reference to a definition in an external document called a content dictionary (or CD). Using XML notation where the element name OMS indicates an OpenMath symbol, the following:

```
<OMS name="sin" cd="transc1"/>
```

represents the usual sine function, as defined in the CD "transc1". A basic OpenMath object is an OpenMath object, although its XML representation will be:

```
<OMOBJ>
  <OMS name="sin" cd="transc1"/>
</OMOBJ>
```

OpenMath objects can be built up recursively in a number of ways. The simplest is function application, for example the expression $\sin(x)$ can be represented by the XML:

```
<OMOBJ>
  <OMA>
    <OMS name="sin" cd="transc1"/>
    <OMV name="x"/>
  </OMA>
</OMOBJ>
```

where OMV introduces a variable and OMA is the application element. Another straightforward method is attribution which as the name suggests can be used to add additional information (for example "the AXIOM command which generated me was ...") to an object without altering its fundamental meaning. More interesting are binding objects which are used to represent an expression containing bound variables, for example:

```
<OMOBJ>
  <OMA>
    <OMS cd="calculus1" name="int"/>
    <OMS cd="transc1" name="sin"/>
  </OMA>
</OMOBJ>
```

represents the integral of the sin function, but the encoding:

```
<OMOBJ>
  <OMA>
```

```

<OMS cd="calculus1" name="int"/>
<OMBIND>
  <OMS cd="fns1" name="lambda"/>
  <OMBVAR> <OMV name="x"/> </OMBVAR>
  <OMA>
    <OMS name="sin" cd="transc1"/>
    <OMV name="x"/>
  </OMA>
</OMBIND>
</OMA>
</OMOBJ>

```

represents $\sin(x)dx$. This may appear overly complicated but it is useful, for example when searching in a database for expressions which match $\sin(y)dy$. The definition of a symbol in the CD specifies whether or not it may be used to bind variables, which is why

```
<OMS cd="calculus1" name="int"/>
```

cannot be used as a binding symbol.

The final kind of OpenMath object is an error which is built up from a symbol describing the error and a sequence of OpenMath objects. For example:

```

<OMOBJ>
  <OME>
    <OMS name="unexpected_symbol" cd="error1">
    <OMS name="sine" cd="transc1">
  </OME>
</OMOBJ>

```

represents the error which might be generated when an application sees a symbol it doesn't recognise from a CD it thought it knew about.

72.1.2 OpenMath Encodings

We have already seen some examples of the XML encoding, but it is by no means the only encoding. In the past there was a functional encoding (which looked like Lisp) and an SGML encoding which evolved into the current XML. Both of these are now obsolete, but there is still a binary encoding described in the standard, which is much more compact than the XML one.

In fact the XML encoding is not 100% XML. When XML was in its infancy the developers of OpenMath realised that it might become significant and decided to add some XML-like features to the SGML encoding so that an OpenMath object could be encoded as valid XML. Thus it is currently the case that any well-formed OpenMath object encoded using the XML encoding as described in the standard is a valid XML document. However, if one uses standard XML tools to generate an OpenMath object in the XML encoding from the DTD given in chapter 4 of the standard, it is possible that the result will not be valid OpenMath,

although in practice this is highly unlikely. To cover all the possibilities allowed by XML would make it much more complicated to write an application to read any OpenMath object from scratch. Whether to adopt XML completely remains a hot topic of debate within the OpenMath community!

Generally speaking, it is not intended that the existing encodings should be readable by a human user or writable by hand. It is desirable that they be compact and it is also desirable that they be linear, but neither of these is a requirement. It is a property of encodings that it is possible to convert between them with no loss of information.

72.1.3 Content Dictionaries

Content Dictionaries (or CDs for short) are the most important, and the most interesting, aspect of OpenMath because they define the meaning of the objects being transmitted. A CD is a collection of related symbols and their definitions, encoded in an XML format. Defining the meaning of a symbol is not a trivial task, and even referring to well-known references can be fraught with pitfalls. Formal definitions and properties can be very useful but time-consuming to produce and verbose, not to mention difficult to get right. A symbol definition in an OpenMath CD consists of the following pieces of information:

- the symbol name;
- a description in plain text;
- optionally, a set of this symbol's properties in plain text
(Commented Mathematical Properties, or CMPs);
- optionally, a set of this symbol's properties encoded in OpenMath
(Formal Mathematical Properties, or FMPs);
- optionally, one or more examples of its use (encoded in OpenMath).

In practice the CMPs and FMPs can come as pairs, and often serve in the place of examples.

A very simple instance of a CD definition is:

```
<CDDefinition>
<Name> log </Name>

<Description>
This symbol represents a binary log function; the first argument is
the base, to which the second argument is log'ed.
It is defined in Abramowitz and Stegun, Handbook of Mathematical
Functions, section 4.1
</Description>
<CMP>
  a^b = c implies log_a c = b
</CMP>
<FMP>
  <OMOBJ>
    <OMA>
      <OMS cd="logic1" name="implies"/>
    </OMA>
  </OMOBJ>
</FMP>
</CDDefinition>
```

```

    <OMS cd="relation1" name="eq"/>

    <OMA>
      <OMS cd="arith1" name="power"/>
      <OMV name="a"/>
      <OMV name="b"/>
    </OMA>
    <OMV name="c"/>
  </OMA>
</OMA>
<OMS cd="relation1" name="eq"/>

  <OMA>
    <OMS cd="transc1" name="log"/>
    <OMV name="a"/>
    <OMV name="c"/>
  </OMA>
  <OMV name="b"/>
</OMA>
</OMA>
</OMOBJ>

</FMP>

<Example>
log 100 to base 10 (which is 2).
<OMOBJ>
  <OMA>
    <OMS cd="transc1" name="log"/>
    <OMF dec="10"/>
    <OMF dec="100"/>
  </OMA>
</OMOBJ>
</Example>

</CDDefinition>

```

Another example would be to print the list

[1, 1/2]

as

```

<OMOBJ>
  <OMA>
    <OMS cd="list1" name="list"/>
    <OMI>1</OMI>
  </OMA>
  <OMS cd="nums1" name="rational"/>
  <OMI>1</OMI>

```

```

    <OMI>2</OMI>
  </OMA>
</OMA>
</OMOBJ>

```

This provides a symbol to represent the log function by giving a pointer to a standard reference book. It provides the property that:

$$a^b = c \rightarrow \log_a(c) = b$$

both as plain text and as OpenMath, and also gives an example of how the symbol is used.

CDs usually consist of related symbols and collections of related CDs can be grouped together, for convenience, as CD Groups. One very important CD Group is that corresponding to the content part of MathML.

It is possible to associate extra information with CDs, in particular type information. Since there are many type systems available, each of which has its own strengths and advocates, the OpenMath community does not mandate any single system. Simple signatures can be encoded using the Simple Type System, while more formal definitions are possible using the Extended Calculus of Constructors. Other associated information can include style sheets for rendering OpenMath symbols in MathML, and mathematical definitions to be used by formal logic systems.

Given the evolutionary nature of mathematics, it is clear that the set of CDs should be forever growing and never complete. Currently there are CDs for high-school mathematics, linear algebra, polynomials and group theory to name a few, and new contributions are always welcome. There is no requirement that applications use the standard set of CDs and it is often very useful to design a "private" CD for a specific purpose.

72.1.4 OpenMath in Action

There is no definitive way in which OpenMath should be used, as the protocol has been designed to be as flexible as possible. Nevertheless many OpenMath applications share common characteristics which we shall discuss here.

Suppose that we wish to have two applications communicating by sending OpenMath objects to each other, e.g. a client program and a computational server. It is unlikely that the internal data structures used by the applications will be OpenMath, and so translation between the internal representations and OpenMath (almost certainly OpenMath encodings rather than objects) will have to take place. The piece of software which does this is usually referred to as a phrase-book.

It is possible to write a generic phrase-book which can handle any piece of OpenMath, but applications where this makes sense are few and far between. In practice an OpenMath phrase book will usually only handle a fixed set of CDs (and hence a fixed set of symbols). What "handle" means will vary from case to case: a computer algebra system will usually try and evaluate its input and return a result or an error, while a typesetter will print its input according to some rendering rules and not return anything. OpenMath carefully avoids

defining what the “right” behaviour is in a given circumstance, and leaves that up to the phrase-book writer. Indeed it is quite possible that a piece of software could have multiple phrase-books associated with it for different purposes. OpenMath symbols should not be regarded as verbs since they are used to construct objects rather than to send commands, and the presence of both nouns and verbs in a CD (e.g. “integral” and “integrate”) is strongly discouraged.

Writing a phrase-book may be non-trivial, and requires an understanding of the semantics of the underlying software. An OpenMath object may not map directly into a private object and vice-versa, for example in some systems a rational number might have to be represented by a float, or a sparse matrix by a dense one.

The OpenMath standard includes a section on compliance, which describes the behaviour of an OpenMath application when certain errors occur. It also insists that all compliant software has the capability to use the XML encoding, to guarantee a degree of interoperability. This is an area where the standard is expected to evolve as more OpenMath applications become available.

72.2 Technical Details[3]

This chapter describes the Axiom implementation of the OpenMath project at INRIA [3]. The code enables the exchange of OpenMath objects between two processes and more generally the input and output of OpenMath objects. First we describe the library API and then we implement the functions used by Axiom.

72.3 The Structure of the API

The library and its API are logically structured in four parts:

- Functions that deal with *devices*, the abstraction from which OpenMath objects are read and written to.
- Functions that read from and write to OpenMath devices. These functions use a simple model that read and write tokens.
- Functions that create I/O structures to be used by devices, so that, for example, an OpenMath object can be read from a file or a socket. This part is extensible by the user.
- Functions that deal with interprocess communication.

72.4 OpenMath Expressions

72.4.1 Expressions

The library understands the following kinds of basic OpenMath expressions:

- integers
- double precision floating-point numbers (64 bits, following IEEE 754)
- byte arrays
- character strings
- symbols
- variables

and the four kinds of constructions:

- applications $e_0(e_1, \dots e_n)$
- errors $s(e_1, \dots e_n)$
- binders $e_1, (v_1, \dots v_n), e_2$
- attributed expressions $[s_1 e_1, \dots s_n e_n]e$

where e_i are OpenMath expressions, v_i are OpenMath variables and s and s_i are OpenMath symbols.

72.4.2 Symbols

Symbols are constructed from a content dictionary (abbreviated as CD in the sequel) and a name. A content dictionary is identified by its name. The API permits the creation of any symbol in any content dictionary: there is nothing that prevents creating symbols that do not belong to a known CD.

72.4.3 Encoding and Decoding OpenMath Expressions

An OpenMath object is encoded as a sequence of bytes that is read and written sequentially. The library views this sequence as a stream of tokens. Expressions are linearized in a way that looks like Lisp with typed parenthesis. For example, the linearization of the application of S to $E_1 \dots E_n$ is:

- indicating that this is an application (a “begin application” token)
- linearizing S

- linearizing E_1, \dots, E_n
- indicating that all arguments have been given (an “end application” token)

The other constructions are linearized the same way (each one with its own begin and end tokens). Note that there is no explicit arity indication so that we don’t have to introduce a special mechanism when we don’t know beforehand how many arguments there are.

To give attributes to an expression, the attributes and their associated values are put before the expression. To give the attributes a_i with values v_i (where a_i are symbols and v_i are OpenMath expressions) to an expression E the process is:

- put a “begin attributed expression” token
- put a “begin attribute pairs” token
- put the symbol a_1 followed by the linearization of v_1 etc
- put an “end attribute pairs” token
- linearize E
- put an “end attributed expression” token

Decoding is done by first querying the type of the next OpenMath token and then invoking the right function to get this particular kind of token.

72.5 Big Integers

The library supports big integers that can potentially be given in various formats. The `OMBigIntType` describes the different possible formats.

```
typedef enum OMBigIntType {
    OMBIunknown = 0, /* this is base 10, digits in normal order */
    OMBIbase10      /* this is base 16, digits in normal order (MSB) */
    OMBigIntBase16
} OMBigIntType;
```

72.6 Functions Dealing with OpenMath Devices

OpenMath expressions are read and written through *devices*. Basically, an OpenMath device has an associated encoding and an I/O method. There are basically two encodings defined and implemented. The first one is a human readable and writable one that can be used for example as the encoding for sending OpenMath objects via e-mail or storing OpenMath objects to files. This encoding is SGML compatible in the sense that it can be used to represent OpenMath objects in SGML texts. I has an XML variant. The second encoding

is a binary one that can be used when compactness and speed of encoding and decoding is important. The encodings are defined by the `OMencodingType` type which is an enumerated type defined as

```
typedef enum OMencodingType
{
    OMencodingUnknown,
    OMencodingBinary,
    OMencodingSGML,
    OMencodingXML} OMencodingType;
```

`OMencodingUnknown` is to be used when creating a device that does not know which kind of encoding will be used. It must be used only for input devices.

A device is created with the following function, given an encoding and an appropriate I/O method:

- `OMdev OMmakeDevice(OMencodingType encoding, OMIO IO)`

Devices are closed with the following function

- `void OMcloseDevice(OMdev dev)`

Whether a device could be used both for reading and writing is entirely dependent on its I/O method.

The user can define its own I/O method as a function returning an `OMIO` object. This could enable him, for example, to use an existing transport protocol to exchange OpenMath expressions or to implement cut-and-paste of OpenMath expression by writing I/O structures that input and output to strings. The I/O section describes the available I/O structures in the library.

An `OMdev` object is a pointer to a structure that contains a lot of state. Almost all functions taking an `OMdev` object modify it. Likewise, an `OMIO` object carries a lot of state.

72.7 Functions to Write OpenMath Expressions to Devices

72.7.1 Beginning and Ending Objects

The following two functions mark the beginning and end of an OpenMath object.

- `OMstatus OMputObject(OMdev dev)`
- `OMstatus OMputEndObject(OMdev dev)`

These functions should be called before and after an OpenMath object is constructed in a device. In particular, the `OMputEndObject` function insures that the object has been completely written if any buffering was used.

72.7.2 Writing Basic Objects

Basic OpenMath objects are written using these functions:

- `OMstatus OMputInt32(OMdev dev, int n)`
- `OMstatus OMputBigInt(OMdev dev, const char *data, int len, int sign, OMbigIntType format)`
- `OMstatus OMputFloat64(OMdev dev, double *f)`
- `OMstatus OMputByteArray(OMdev dev, const char *data, int len)`
- `OMstatus OMputString(OMdev dev, const char *s)`
- `OMstatus OMputVar(OMdev dev, const char *name)`
- `OMstatus OMputSymbol(OMdev dev, const char *cd, const char *name)`

The `char *` arguments of `OMputString`, `OMputVar` and `OMputSymbol` are null-terminated strings. There are other functions that accept non null-terminated arrays of characters with their length. These are

- `OMstatus OMputStringN(OMdev dev, const char *str, int len)`
- `OMstatus OMputVarN(OMdev dev, const char *var, int len)`
- `OMstatus OMputSymbolN(OMdev dev, const char *cd, int clen, const char *name, int nlen)`

The format for the `data` argument of the `OMputBigInt` function is given by `format`. When `format` is `OMBIbase10`, it is the sequence of character of its base 10 representation without sign (most significant digit first). The sign of the big integer is given by the `sign` argument that should be an integer greater or equal to zero for a positive integer and less than zero for a negative one. For example, the following line outputs the value of 20! to `dev`:

```
OMputBigInt(dev, "265252859812191058636308480000000", 33, 1, OMBIbase10);
```

72.7.3 Writing Structured Objects

The following functions are used to mark the beginning and end of the structured objects. They should be called in nested pairs, correctly bracketed:

- `OMstatus OMputApp(OMdev dev)`
- `OMstatus OMputEndApp(OMdev dev)`
- `OMstatus OMputAttr(OMdev dev)`
- `OMstatus OMputEndAttr(OMdev dev)`

- `OMstatus OMputBind(OMdev dev)`
- `OMstatus OMputEndBind(OMdev dev)`
- `OMstatus OMputBVar(OMdev dev)`
- `OMstatus OMputEndBVar(OMdev dev)`
- `OMstatus OMputAtp(OMdev dev)`
- `OMstatus OMputEndAtp(OMdev dev)`
- `OMstatus OMputError(OMdev dev)`
- `OMstatus OMputEndError(OMdev dev)`

Here is an example showing how to use these functions to output $\sin x + y$, where x and y are represented as variables and \sin is the symbol whose name is `sin` in the `Basic` content dictionary. This can be done using the following sequence:

```
OMputObject(dev);
OMputApp(dev);
  OMputSymbol(dev, "Basic", "sin");
  OMputApp(dev)
    OMputSymbol(dev, "Basic", "+");
    OMputVar(dev, "x");
    OMputVar(dev, "y");
  OMputEndApp(dev);
OMputEndApp(dev);
OMputEndObject(dev);
```

72.8 Functions to Extract OpenMath Expressions from Devices

72.8.1 Testing the type of the current token

The first step in decoding an expression from a device is to call the `OMgetType` function

- `OMstatus OMgetType(OMdev dev, OMtokenType *type)`

so that the correct function can be called to recover the current token.

`OMgetType` returns via its `type` argument an `OMtokenType` object indicating the type of the next object to be read from the device. `OMtokenType` is an enumerated type defined as

```
typedef enum OMtokenType {
  OMtokenUnknown, /* error catching trick */
  OMtokenInt32,
```

```

OMtokenBigInt,
OMtokenFloat64,
OMtokenByteArray,
OMtokenVar,
OMtokenString,
OMtokenSymbol,
OMtokenComment,
OMtokenApp,    OMtokenEndApp,
OMtokenAttr,   OMtokenEndAttr,
OMtokenAtp,    OMtokenEndAtp,
OMtokenError,  OMtokenEndError,
OMtokenObject, OMtokenEndObject,
OMtokenBind,   OMtokenEndBind,
OMtokenBVar,   OMtokenEndBVar,
} OMTokenType;

```

Note that the type of the current token can be tested multiple times. Two successive calls to `OMgetType` will always return the same result if no other `OMget...` function was called in between.

72.8.2 Extracting the current token

The following functions are used to read the basic OpenMath objects from devices:

- `OMstatus OMgetInt32(OMdev dev, int *i)`
- `OMstatus OMgetFloat64(OMdev dev, double *d)`
- `OMstatus OMgetBigInt(OMdev dev, char **data, int *len, int *sign, OMbigIntType *fmt)`
- `OMstatus OMgetBigIntN(OMdev dev, char *data, int len, int *sign, OMbigIntType *fmt)`
- `OMstatus OMgetByteArray(OMdev dev, char **data, int *len)`
- `OMstatus OMgetByteArrayN(OMdev dev, char *data, int len)`
- `OMstatus OMgetString(OMdev dev, char **str)`
- `OMstatus OMgetStringN(OMdev dev, char *str, int len)`
- `OMstatus OMgetVar(OMdev dev, char **var)`
- `OMstatus OMgetVarN(OMdev dev, char *var, int len)`
- `OMstatus OMgetSymbol(OMdev dev, char **cd, char **name)`
- `OMstatus OMgetSymbolN(OMdev dev, char *cd, int clen, char *name, int nlen)`

The functions that return variable size data exist in two versions. A simple version that does the necessary memory allocation itself (using `OMmalloc`) and a version (suffixed with `N`) that lets the user do the allocation itself. The size of the needed area can be determined with the following function:

- `int OMgetLength(OMdev dev)` returns the length of the next object.

that works for big integers, byte arrays, strings and variables. For symbols, the following function returns both the length of the content dictionary name and the length of the symbol name:

- `OMstatus OMgetSymbolLength(OMdev dev, int *klen, int *nlen)`

When the current token does not carry any data i.e. when `OMgetType` returns a marker, i.e. one of:

- `OMtokenApp,`
- `OMtokenEndApp,`
- `OMtokenAttr,`
- `OM tokenEndAttr,`
- `OMtokenAtp,`
- `OMtokenEndAtp,`
- `OMtokenError,`
- `OMtokenEndError,`
- `OMtokenObject,`
- `OMtokenEndObject,`
- `OMtokenBind,`
- `OMtokenEndBind,`
- `OMtokenBVar`
- `OMtokenEndBVar`

it is necessary to call the correct function to remove the marker. The available functions are

- `OMstatus OMgetObject(OMdev dev)`
- `OMstatus OMgetEndObject(OMdev dev)`
- `OMstatus OMgetApp(OMdev dev)`

72.8. FUNCTIONS TO EXTRACT OPENMATH EXPRESSIONS FROM DEVICES1117

- OMstatus OMgetEndApp(OMdev dev)
- OMstatus OMgetAttr(OMdev dev)
- OMstatus OMgetEndAttr(OMdev dev)
- OMstatus OMgetAtp(OMdev dev)
- OMstatus OMgetEndAtp(OMdev dev)
- OMstatus OMgetBind(OMdev dev)
- OMstatus OMgetEndBind(OMdev dev)
- OMstatus OMgetBVar(OMdev dev)
- OMstatus OMgetEndBVar(OMdev dev)
- OMstatus OMgetError(OMdev dev)
- OMstatus OMgetEndError(OMdev dev)

All the previous functions return OMsuccess when they succeed. When they return something else, there has been a problem such as calling the wrong function (OMgetApp when there is not a “beginning of application” mark) or a system error.

The sequence of calls to read an expression is thus completely similar (if we omit the calls to OMgetType) to the sequence of calls to write the expression. For example, the previous expression $(\sin x + y)$ can be recovered via the sequence:

```
OMgetObject(dev);
OMgetApp(dev);
  OMgetSymbol(dev, ...);
  OMgetApp(dev);
    OMgetSymbol(dev, ...);
    OMgetVar(dev, ...);
    OMgetVar(dev, ...);
  OMgetEndApp(dev);
OMgetEndApp(dev);
OMgetEndObject(dev);
```

OMgetInt32(OMdev dev, int *i) returns the integer through its i argument.

OMgetBigInt(OMdev dev, char **data, int *len, int *sign, OMbigIntType *fmt)

returns the data corresponding to the big integer in data, its length in len, its sign in sign and its format in fmt.

OMgetBigIntN(OMdev dev, char *data, int len, int *sign, OMbigIntType *fmt)

copies the data corresponding to the big integer in **data** buffer that should be (at least) **len** characters long. The sign and format are returned in the **sign** and **fmt** arguments.

OMgetByteArray(OMdev dev, char **data, int *len) returns the byte array through its **data** argument. Its length is returned via the **len** argument.

OMgetByteArrayN(OMdev dev, char *data, int len) copies the byte array in the **data** buffer that should be (at least) **len** characters long.

OMgetString(OMdev dev, char **str) returns the string through its **str** argument.

OMgetStringN(OMdev dev, char *str, int len) copies the string in the **str** buffer whose length should be (at least) **len**. If **len** is greater than the actual length of the string, a null character is added at the end of **str**.

OMgetVar(OMdev dev, char **var) returns the name of the variable (as a null-terminated string) in its **var** argument

OMgetVarN(OMdev dev, char *var, int len) copies the name of the variable in the **var** buffer, whose length should be (at least) **len**. If **len** is greater than the actual length of the variable name, a null character is added at the end of **var**.

OMgetSymbol(OMdev dev, char **cd, char **name) returns the content dictionary and the name of the symbol through the **cd** and **name** arguments.

OMgetSymbolN(OMdev dev, char *cd, int clen, char *name, int nlen) copies the content dictionary and the name of the symbols in the **cd** and **name** buffers. **cd** should be at least **clen** character long and **name** should be at least **nlen** long. When there is enough room (based on **clen** or **nlen**) a null character is added after the last character of the name (**cd** or **name**).

72.9 Comments in the SGML/XML Encodings

The library can also output and read comments (SGML/XML comments) with the following functions:

- **OMstatus OMputComment**(OMdev dev, char *comment)
- **OMstatus OMputCommentN**(OMdev dev, char *comment, int len)
- **OMstatus OMgetComment**(OMdev dev, char **comment)
- **OMstatus OMgetCommentN**(OMdev dev, char *comment, int len)

By default, comments are silently ignored by the library when reading OpenMath objects (and writing them using the binary encoding). The function

- **OMbool OMignoreComment**(OMdev dev, OMbool set)

changes this behaviour. When called with **OMfalse**, comments are passed to the application: the **OMgetType** function will return **OMtokenComment** when the current token is a comment and the **OMgetComment** or **OMgetCommentN** functions should be used to get the comments. When **OMignoreComment** is called with **OMtrue**, comments are ignored.

72.10 I/O Functions for Devices

We provide four functions that produce OMIO objects for devices. These functions provide I/O through the `stdio` library (on FILE object), file descriptors and character strings.

- OMIO `OMmakeIOFile(FILE *f)` associates the device with the file pointer `f`.
- OMIO `OMmakeIOfd(int fd)` associates the device with the file descriptor `fd`.
- OMIO `OMmakeIOHandle(HANDLE handle)` associates the device with a file handle *Windows specific version of `OMmakeIOfd().fd`.
- OMIO `OMmakeIOString(char **s)` associates the device with a string.

For example, the following code opens a device that reads from standard input:

```
dev = OMmakeDevice(OMencodingSGML, OMmakeIOFile(stdin));
```

The `OMmakeIOString` builds an input device that reads from a string or an output device that writes to a string. For input, `s` must point to a character string (null terminated). For output, `s` will point to a string allocated by the library (note that the string `s` points to can be reallocated by the library).

72.11 Communications

A communication layer can be put above the device layer. In fact, the I/O structure in a device provides all the necessary support to use any transmission or communication means. This library directly provides some connection-oriented, client-server facilities (based on TCP).

A set of functions are used to set up connections. Connections are described by the `OMconn` type. An `OMconn` is a (pointer to a) structure with two user-accessible fields `in` and `out`. `in` is a pointer to a device to be used for input. `out` is pointer to a device to be used for output. These devices use the binary encoding.

An `OMconn` object is made with the following function:

- OMconn `OMmakeConn(int timeout)`

where `timeout` is a timeout for the connection, expressed in milliseconds.

- OMdev `OMconnIn(OMconn conn)` returns the input device associated with the connection.
- OMdev `OMconnOut(OMconn conn)` returns the output device associated with the connection.

72.11.1 Functions to Initiate an OMconn

The functions we provide can be divided in two classes. The first one simply establishes an interprocess communication using IP addresses. The second one provides functions that can be used to launch a server. The addresses used are then generated by the library.

Simple Connections Functions

The following functions allow a client OpenMath application to contact an OpenMath server at a specified address:

- `OMstatus OMconnTCP(OMconn conn, char *machine, int port)`
- `OMstatus OMconnUnix(OMconn conn, char *file)`

These functions first physically establish the connection. Then, they enter negotiation with the server (they send the first message). When they return, the negotiation is finished and the devices in the `conn` argument are ready.

On the server side, the following functions provide bindings at specified addresses and take care of the negotiation:

- `OMstatus OMbindTCP(OMconn conn, int port)`
- `OMstatus OMbindUnix(OMconn conn, char *file)`

All four the previous functions block until the connection is established (and negotiation is over) or the timeout of the `conn` argument is reached.

The following function returns the file descriptor associated with a device. This is intended to be used when there is a need to poll the device (through the `select` or `poll` system calls).

- `OMdeviceFd(OMdev dev)`

Functions that Launch Servers

These functions provide the same functionalities for launching a server that were provided in the ASAP library.

In this model, the client calls `OMlaunch` with a machine name `mach` and a string `cmd` that is executed via `rsh` on machine `mach` as a shell command line. This command is supposed to launch the server program. The command is executed in an environment (in the UNIX sense) where some variables are associated with an address on the machine that runs the client. The server can then connect to the client with the `OMserveClient` function.

If the machine name is `localhost`, the command is started on the same machine (without calling `rsh`).

- `OMstatus OMlaunchEnv(OMconn conn, char *machine, char *command, char *env)`

- `OMstatus OMlaunch(OMconn conn, char *machine, char *command)`
- `OMstatus OMserveClient(OMconn conn)`

The environment variables passed to the server (launched program) are `OM_CALLER_UNIX_SOCKET` (when a local connection is required) and `OM_CALLER_MACHINE` and `OM_CALLER_PORT` (for internet connections).

The `OMlaunchEnv` function enables the command to be run with a particular environment (in the UNIX sense). For example to run a `plot` server on the `kama` machine, we could use a piece of code such as

```
conn = OMmakeConn(2000);
OMlaunchEnv(conn, "kama", "plot", "DISPLAY=rati:0 PATH=/users/bin");
```

Termination

- `OMstatus OMconnClose(OMconn conn)`

72.12 Parameters

The library internally uses three functions that can be supplied by the user.

- `extern void *(*OMmalloc) (size_t size)`
- `extern void *(*OMrealloc) (void *ptr, size_t size)`
- `extern void (*OMfree) (void *ptr)`
- `OMmalloc` is used for all memory allocations in the library. The default value is the `malloc` function.
- `OMfree` is used for deallocations. The default value is the `free` function.
- `OMfatal` is invoked when a fatal error is detected in the library (for example when memory allocation failed or when an inconsistency is detected in the library code data structures). The default value just does an `exit`.

`OMfatal` is declared as `extern void (*OMfatal)(OMstatus status)`. All memory allocations and deallocations in the library are done through the `OMmalloc` and `OMfree` functions.

72.13 Miscellaneous Functions and Variables

- `char *OMstatusToString(OMstatus status)` converts a status to a human readable string.

- `char *OMtokenTypeToString(OMtokenType ttype)` converts a `tokenType` to a human readable string.
- `OMencodingType OMgetDeviceEncoding(OMdev dev)` returns the encoding actually used by the device.
- `char *OMlibDynamicInfo(void)`
- `extern const char *OMlibVersion` is the version of the library.
- `extern const char *OMlibInfo` contains some textual information about the library.

72.14 The OM.h header file

```
#ifndef __OM_h__
#define __OM_h__

/*
 *
 *          All types used through API.
 */

/* These types are anonymized by the mean of a generic pointer.
 * You should not allocate or dereference objects of these types.
 * API (hopefully) provides you with all needed methods.
 * If you find any that are not included, please refer to
 * us rather than using private structures.
 * ie: If you need to do something like
 *   malloc(sizeof(OMdevStruct));
 * or
 *   OMdevStruct * pDev;
 *   pDev->anyField = something;
 * this probably means we need to discuss your problem.
 */

/* A device is an abstraction for put/get of OpenMath tokens */

72.15 Axiom OpenMath stub functions

These stub functions will eventually be expanded to handle OpenMath. See the OpenMath-Device domain in Volume 10.3. Note that the argument list for the Spad functions does not always match the argument list specified in the OpenMath specification.

There are 4 known OpenMath encodings which are set up in the OpenMathEncoding domain in Volume 10.3.

- Unknown
- Binary
- XML
- SGML

72.15.1 Axiom specific functions

This is used in OpenMathPackage in Volume 10.4.

```

(read OMdev)           -> LispObject
(listCDs)              -> List(String)
(listSymbols)          -> List(String)
(supportsCD cd)        -> Boolean
(supportsSymbol cd name) -> Boolean

```

72.15.2 defun om-Read

Read an OpenMath object from dev.
 — defun om-Read —

```
(defun om-Read (dev)
  (declare (ignore dev)))
```

72.15.3 defun om-listCDs

Lists all of the CDs supported by Axiom.

— **defun om-listCDs** —

```
(defun om-listCDs ())
```

72.15.4 defun om-listSymbols

Lists all the symbols in CD

— **defun om-listSymbols** —

```
(defun om-listSymbols ())
```

72.15.5 defun om-supportsCD

Return true if Axiom supports this CD.

— **defun om-supportsCD** —

```
(defun om-supportsCD (cd)
  (declare (ignore cd)))
```

72.15.6 defun om-supportsSymbol

— **defun om-supportsSymbol** —

```
(defun om-supportsSymbol (cd name)
  (declare (ignore cd name)))
```

72.15.7 Lisp conversion functions

The lisp conversion functions are:

(toDev	LispObject)	-> OMdev
(fromDev	OMdev)	-> LispObject
(toStatus	LispObject)	-> LispObject
(fromStatus	OMstatus)	-> LispObject
(toEncodingType	LispObject)	-> OMencodingType
(fromEncodingType	OMencodingType)	-> LispObject
(toBigNumStr	LispObject)	-> char *
(fromBigNumStr	char *,int,int, OMbigIntType)	-> LispObject
(toConn	LispObject)	-> OMconn
(fromConn	OMconn)	-> LispObject
(toCString	LispObject)	-> char **
(fromCString	char **)	-> LispObject
(lispStringFromCString	LispObject)	-> LispObject
(cStringFromLispString	LispObject)	-> LispObject

72.15.8 defun om-setDevEncoding

This sets the encoding used for reading or writing OpenMath objects to or from dev to enc.

— defun om-setDevEncoding —

```
(defun om-setDevEncoding (dev enc)
  (declare (ignore dev enc)))
```

72.15.9 Device manipulation functions

(openFileDev	LispObject, ints, ...)	-> LispObject
(openStrDev	LispObject, LispObject, LispObject)	-> LispObject
(closeDev	LispObject, LispObject)	-> LispObject

72.15.10 defun om-openFileDev

This opens file fname for reading or writing OpenMath objects. The mode can be “r” for read, “w” for write, or “a” for append.

— defun om-openFileDev —

```
(defun om-openFileDev (fname fmode enc)
  (declare (ignore fname fmode enc)))
```

72.15.11 defun om-openStringDev

This opens the string str for reading and writing OpenMath objects in encoding enc.

— **defun om-openStringDev** —

```
(defun om-openStringDev (str enc)
  (declare (ignore str enc)))
```

—————

72.15.12 defun om-closeDev

This closes dev, flushing output if necessary.

— **defun om-closeDev** —

```
(defun om-closeDev (dev)
  (declare (ignore dev)))
```

—————

72.15.13 Connection manipulation functions

These are covered in the OpenMathConnection domain in Volume 10.3.

```
(makeConn      LispObject, LispObject) -> LispObject
(closeConn     LispObject, LispObject) -> LispObject
(getConnInDev  LispObject, LispObject) -> LispObject
(getConnOutDev LispObject, LispObject) -> LispObject
```

72.15.14 defun om-makeConn

— **defun om-makeConn** —

```
(defun om-makeConn (conn)
  (declare (ignore conn)))
```

—————

72.15.15 defun om-closeConn

— **defun om-closeConn** —

```
(defun om-closeConn (conn)
  (declare (ignore conn)))
```

72.15.16 defun om-getConnInDev

— defun om-getConnInDev —

```
(defun om-getConnInDev (conn)
  (declare (ignore conn)))
```

72.15.17 defun om-getConnOutDev

— defun om-getConnOutDev —

```
(defun om-getConnOutDev (conn)
  (declare (ignore conn)))
```

72.15.18 Client/Server functions

These are covered in the OpenMathConnection domain in Volume 10.3. See OMconn.h

```
(bindTCP    LispObject, LispObject, LispObject) -> LispObject
(connectTCP LispObject, int, ...)               -> LispObject
```

72.15.19 defun om-bindTCP

— defun om-bindTCP —

```
(defun om-bindTCP (conn port)
  (declare (ignore conn port)))
```

72.15.20 defun om-connectTCP

— defun om-connectTCP —

```
(defun om-connectTCP (conn host port)
  (declare (ignore conn host port)))
```

—————

72.15.21 Device input/output functions

Most of these functions are in the OpenMathDevice domain in Volume 10.3. The only exception seems to be the om-stringPtrToString and om-stringToStringPtr functions which are called in the domains that export primitives. Currently these are:

- Complex (10.3)
- DoubleFloat (10.3)
- Float (10.3)
- Fraction (10.3)
- Integer (10.3)
- List (10.3)
- SingleInteger (10.3)
- String (10.3)
- Symbol (10.3)
- ExpressionToOpenMath (10.4)
- OpenMathPackage (10.4)

Note that putSymbol2 is not implemented.

(getApp	LispObject, LispObject)	-> LispObject
(getAtp	LispObject, LispObject)	-> LispObject
(getAttr	LispObject, LispObject)	-> LispObject
(getBind	LispObject, LispObject)	-> LispObject
(getBVar	LispObject, LispObject)	-> LispObject
(getByteArray	LispObject, LispObject)	-> LispObject
(getEndApp	LispObject, LispObject)	-> LispObject
(getEndAtp	LispObject, LispObject)	-> LispObject
(getEndAttr	LispObject, LispObject)	-> LispObject

```

(getEndBind      LispObject, LispObject) -> LispObject
(getEndBVar      LispObject, LispObject) -> LispObject
(getEndError     LispObject, LispObject) -> LispObject
(getEndObject    LispObject, LispObject) -> LispObject
(getError        LispObject, LispObject) -> LispObject
(getFloat        LispObject, LispObject) -> LispObject

(putSymbol2      LispObject, int nargs, ...) -> LispObject
(putVar          LispObject, LispObject, LispObject) -> LispObject
(stringPtrToString LispObject, LispObject) -> LispObject
(stringToStringPtr LispObject, LispObject) -> LispObject

```

72.15.22 defun om-getApp

Reads a begin application token from dev.

— **defun om-getApp** —

```

(defun om-getApp (dev)
  (declare (ignore dev)))

```

—————

72.15.23 defun om-getAtp

Reads a begin attribute pair token from dev.

— **defun om-getAtp** —

```
(defun om-getAtp (dev)
  (declare (ignore dev)))
```

72.15.24 defun om-getAttr

Reads a begin attribute token from dev

— **defun om-getAttr** —

```
(defun om-getAttr (dev)
  (declare (ignore dev)))
```

72.15.25 defun om-getBind

Reads a begin binder token from dev.

— **defun om-getBind** —

```
(defun om-getBind (dev)
  (declare (ignore dev)))
```

72.15.26 defun om-getBVar

Reads a begin bound variable list token from dev.

— **defun om-getBVar** —

```
(defun om-getBVar (dev)
  (declare (ignore dev)))
```

72.15.27 defun om-getByteArray

Reads a byte array from dev.

— **defun om-getByteArray** —

```
(defun om-getByteArray (dev))
```

72.15.28 defun om-getEndApp

Reads an end application token from dev

— **defun om-getEndApp** —

```
(defun om-getEndApp (dev)
  (declare (ignore dev)))
```

72.15.29 defun om-getEndAtp

Reads an end attribute pair token from dev.

— **defun om-getEndAtp** —

```
(defun om-getEndAtp (dev)
  (declare (ignore dev)))
```

72.15.30 defun om-getEndAttr

Reads an end attribute token from dev.

— **defun om-getEndAttr** —

```
(defun om-getEndAttr (dev)
  (declare (ignore dev)))
```

72.15.31 defun om-getEndBind

Reads an end binder token from dev.

— **defun om-getEndBind** —

```
(defun om-getEndBind (dev)
  (declare (ignore dev)))
```

72.15.32 defun om-getEndBVar

Reads an end bound variable list token from dev.

— **defun om-getEndBVar** —

```
(defun om-getEndBVar (dev)
  (declare (ignore dev)))
```

72.15.33 defun om-getEndError

Reads an end error token from dev.

— **defun om-getEndError** —

```
(defun om-getEndError (dev)
  (declare (ignore dev)))
```

72.15.34 defun om-getEndObject

Reads an end object token from dev.

— **defun om-getEndObject** —

```
(defun om-getEndObject (dev)
  (declare (ignore dev)))
```

72.15.35 defun om-getError

Reads a begin error token from dev.

— **defun om-getError** —

```
(defun om-getError (dev)
  (declare (ignore dev)))
```

—————

72.15.36 defun om-getFloat

Reads a float from dev.

— **defun om-getFloat** —

```
(defun om-getFloat (dev)
  (declare (ignore dev)))
```

—————

72.15.37 defun om-getInt

Reads an integer from dev.

— **defun om-getInt** —

```
(defun om-getInt (dev)
  (declare (ignore dev)))
```

—————

72.15.38 defun om-getObject

Reads a begin object token from dev.

— **defun om-getObject** —

```
(defun om-getObject (dev)
  (declare (ignore dev)))
```

—————

72.15.39 defun om-getString

Reads a string from dev.

— **defun om-getString** —

```
(defun om-getString (dev)
  (declare (ignore dev)))
```

72.15.40 defun om-getSymbol

Reads a symbol from dev.

— **defun om-getSymbol** —

```
(defun om-getSymbol (dev)
  (declare (ignore dev)))
```

72.15.41 defun om-getType

Returns the type of the next object on dev.

— **defun om-getType** —

```
(defun om-getType (dev)
  (declare (ignore dev)))
```

72.15.42 defun om-getVar

Reads a variable from dev.

— **defun om-getVar** —

```
(defun om-getVar (dev)
  (declare (ignore dev)))
```

72.15.43 defun om-putApp

Writes a begin application token to dev.

— **defun om-putApp** —

```
(defun om-putApp (dev)
  (declare (ignore dev)))
```

—————

72.15.44 defun om-putAtp

This writea a begin application pair token to dev.

— **defun om-putAtp** —

```
(defun om-putAtp (dev)
  (declare (ignore dev)))
```

—————

72.15.45 defun om-putAttr

This writes a begin attribute token to dev.

— **defun om-putAttr** —

```
(defun om-putAttr (dev)
  (declare (ignore dev)))
```

—————

72.15.46 defun om-putBind

This writes a begin binder token to dev.

— **defun om-putBind** —

```
(defun om-putBind (dev)
  (declare (ignore dev)))
```

—————

72.15.47 defun om-putBVar

This writes a begin bound variable list token to dev.

— **defun om-putBVar** —

```
(defun om-putBVar (dev)
  (declare (ignore dev)))
```

—————

72.15.48 defun om-putByteArray

This writes a byte array to dev.

— **defun om-putByteArray** —

```
(defun om-putByteArray (dev b)
  (declare (ignore dev b)))
```

—————

72.15.49 defun om-putEndApp

This writes an end application token to dev.

— **defun om-putEndApp** —

```
(defun om-putEndApp (dev)
  (declare (ignore dev)))
```

—————

72.15.50 defun om-putEndAtp

This writes an end attribute pair to dev.

— **defun om-putEndAtp** —

```
(defun om-putEndAtp (dev)
  (declare (ignore dev)))
```

—————

72.15.51 defun om-putEndAttr

This writes an end attribute token to dev.

— **defun om-putEndAttr** —

```
(defun om-putEndAttr (dev)
  (declare (ignore dev)))
```

—————

72.15.52 defun om-putEndBind

This writes an end binder token to dev.

— **defun om-putEndBind** —

```
(defun om-putEndBind (dev)
  (declare (ignore dev)))
```

—————

72.15.53 defun om-putEndBVar

This writes and end bound variable list token to dev

— **defun om-putEndBVar** —

```
(defun om-putEndBVar (dev)
  (declare (ignore dev)))
```

—————

72.15.54 defun om-putEndError

This writes an end error token to dev

— **defun om-putEndError** —

```
(defun om-putEndError (dev)
  (declare (ignore dev)))
```

—————

72.15.55 defun om-putEndObject

This writes an end object token to dev.

— **defun om-putEndObject** —

```
(defun om-putEndObject (dev)
  (declare (ignore dev)))
```

72.15.56 defun om-putError

This writes a begin error token to dev.

— **defun om-putError** —

```
(defun om-putError (dev)
  (declare (ignore dev)))
```

72.15.57 defun om-putFloat

This writes the float f to dev.

— **defun om-putFloat** —

```
(defun om-putFloat (dev f)
  (declare (ignore dev f)))
```

72.15.58 defun om-putInt

This writes the integer i to dev

— **defun om-putInt** —

```
(defun om-putInt (dev i)
  (declare (ignore dev i)))
```

Chapter 74

Monitoring execution

MONITOR

This file contains a set of function for monitoring the execution of the functions in a file. It constructs a hash table that contains the function name as the key and monitor-data structures as the value

The technique is to use a :cond parameter on trace to call the monitor-incr function to incr the count every time a function is called

```
*monitor-table*                                HASH TABLE
  is the monitor table containing the hash entries
*monitor-nrlibs*                               LIST of STRING
  list of nrlib filenames that are monitored
*monitor-domains*                             LIST of STRING
  list of domains to monitor-report (default is all exposed domains)
monitor-data                                  STRUCTURE
  is the defstruct name of records in the table
  name is the first field and is the name of the monitored function
  count contains a count of times the function was called
  monitorp is a flag that skips counting if nil, counts otherwise
  sourcefile is the name of the file that contains the source code
```

***** SETUP, SHUTDOWN *****

```
monitor-inittable ()                          FUNCTION
  creates the hashtable and sets *monitor-table*
  note that it is called every time this file is loaded
monitor-end ()                                FUNCTION
  unhooks all of the trace hooks
```

***** TRACE, UNTRACE *****

```

monitor-add (name &optional sourcefile)      FUNCTION
  sets up the trace and adds the function to the table
monitor-delete (fn)                          FUNCTION
  untraces a function and removes it from the table
monitor-enable (&optional fn)                FUNCTION
  starts tracing for all (or optionally one) functions that
  are in the table
monitor-disable (&optional fn)              FUNCTION
  stops tracing for all (or optionally one) functions that
  are in the table

```

***** COUNTING, RECORDING *****

```

monitor-reset (&optional fn)                FUNCTION
  reset the table count for the table (or optionally, for a function)
monitor-incr (fn)                            FUNCTION
  increments the count information for a function
  it is called by trace to increment the count
monitor-decr (fn)                            FUNCTION
  decrements the count information for a function
monitor-info (fn)                            FUNCTION
  returns the monitor-data structure for a function

```

***** FILE IO *****

```

monitor-write (items file)                  FUNCTION
  writes a list of symbols or structures to a file
monitor-file (file)                         FUNCTION
  will read a file, scan for defuns, monitor each defun
  NOTE: monitor-file assumes that the file has been loaded

```

***** RESULTS *****

```

monitor-results ()                          FUNCTION
  returns a list of the monitor-data structures
monitor-untested ()                         FUNCTION
  returns a list of files that have zero counts
monitor-tested (&optional delete)           FUNCTION
  returns a list of files that have nonzero counts
  optionally calling monitor-delete on those functions

```

***** CHECKPOINT/RESTORE *****

```

monitor-checkpoint (file)                   FUNCTION
  save the *monitor-table* in a loadable form
monitor-restore (file)                      FUNCTION
  restore a checkpointed file so that everything is monitored

```

***** ALGEBRA *****

```

monitor-autoload ()                         FUNCTION
  traces autoload of algebra to monitor corresponding source files

```

NOTE: this requires the /spad/int/algebra directory

monitor-dirname (args) FUNCTION
 expects a list of 1 libstream (loadvol's arglist) and monitors the source
 this is a function called by monitor-autoload

monitor-nrllib (nrllib) FUNCTION
 takes an nrllib name as a string (eg POLY) and returns a list of
 monitor-data structures from that source file

monitor-report () FUNCTION
 generate a report of the monitored activity for domains in
 monitor-domains

monitor-spadfile (name) FUNCTION
 given a spad file, report all nrllibs it creates
 this adds each nrllib name to *monitor-domains* but does not
 trace the functions from those domains

monitor-percent () FUNCTION
 ratio of (functions executed)/(functions traced)

monitor-apropos (str) FUNCTION
 given a string, find all monitored symbols containing the string
 the search is case-insensitive. returns a list of monitor-data items

for example:

suppose we have a file "/u/daly/testmon.lisp" that contains:

```
(defun foo1 () (print 'foo1))
(defun foo2 () (print 'foo2))
(defun foo3 () (foo1) (foo2) (print 'foo3))
(defun foo4 () (print 'foo4))
```

an example session is:

```
; FIRST WE LOAD THE FILE (WHICH INITIS *monitor-table*)
```

```
>(load "/u/daly/monitor.lisp")
Loading /u/daly/monitor.lisp
Finished loading /u/daly/monitor.lisp

;;; The technique is to use a :cond parameter on trace to call the
;;; monitor-incr function to incr the count every time a function is called
;;;
;;; *monitor-table*                                HASH TABLE
;;;   is the monitor table containing the hash entries
;;; *monitor-nrlibs*                                LIST of STRING
;;;   list of nrllib filenames that are monitored
;;; *monitor-domains*                                LIST of STRING
;;;   list of domains to monitor-report (default is all exposed domains)
;;; monitor-data                                    STRUCTURE
;;;   is the defstruct name of records in the table
;;;   name is the first field and is the name of the monitored function
;;;   count contains a count of times the function was called
;;;   monitorp is a flag that skips counting if nil, counts otherwise
;;;   sourcefile is the name of the file that contains the source code
;;;
;;; ***** SETUP, SHUTDOWN *****
;;;
;;; monitor-inittable ()                            FUNCTION
;;;   creates the hashtable and sets *monitor-table*
;;;   note that it is called every time this file is loaded
;;; monitor-end ()                                  FUNCTION
;;;   unhooks all of the trace hooks
;;;
;;; ***** TRACE, UNTRACE *****
;;;
;;; monitor-add (name &optional sourcefile)         FUNCTION
;;;   sets up the trace and adds the function to the table
;;; monitor-delete (fn)                             FUNCTION
;;;   untraces a function and removes it from the table
;;; monitor-enable (&optional fn)                   FUNCTION
;;;   starts tracing for all (or optionally one) functions that
;;;   are in the table
;;; monitor-disable (&optional fn)                 FUNCTION
```

```

;;; stops tracing for all (or optionally one) functions that
;;; are in the table
;;;
;;; ***** COUNTING, RECORDING *****
;;;
;;; monitor-reset (&optional fn)                FUNCTION
;;; reset the table count for the table (or optionally, for a function)
;;; monitor-incr (fn)                            FUNCTION
;;; increments the count information for a function
;;; it is called by trace to increment the count
;;; monitor-decr (fn)                            FUNCTION
;;; decrements the count information for a function
;;; monitor-info (fn)                            FUNCTION
;;; returns the monitor-data structure for a function
;;;
;;; ***** FILE IO *****
;;;
;;; monitor-write (items file)                   FUNCTION
;;; writes a list of symbols or structures to a file
;;; monitor-file (file)                         FUNCTION
;;; will read a file, scan for defuns, monitor each defun
;;; NOTE: monitor-file assumes that the file has been loaded
;;;
;;; ***** RESULTS *****
;;;
;;; monitor-results ()                           FUNCTION
;;; returns a list of the monitor-data structures
;;; monitor-untested ()                         FUNCTION
;;; returns a list of files that have zero counts
;;; monitor-tested (&optional delete)           FUNCTION
;;; returns a list of files that have nonzero counts
;;; optionally calling monitor-delete on those functions
;;;
;;; ***** CHECKPOINT/RESTORE *****
;;;
;;; monitor-checkpoint (file)                   FUNCTION
;;; save the *monitor-table* in a loadable form
;;; monitor-restore (file)                     FUNCTION
;;; restore a checkpointed file so that everything is monitored
;;;
;;; ***** ALGEBRA *****
;;;
;;; monitor-autoload ()                         FUNCTION
;;; traces autoload of algebra to monitor corresponding source files
;;; NOTE: this requires the /spad/int/algebra directory
;;; monitor-dirname (args)                     FUNCTION
;;; expects a list of 1 libstream (loadvol's arglist) and monitors the source
;;; this is a function called by monitor-autoload
;;; monitor-nrllib (nrllib)                   FUNCTION
;;; takes an nrllib name as a string (eg POLY) and returns a list of

```

```

;;; monitor-data structures from that source file
;;; monitor-report () FUNCTION
;;; generate a report of the monitored activity for domains in
;;; *monitor-domains*
;;; monitor-spadfile (name) FUNCTION
;;; given a spad file, report all nrlibs it creates
;;; this adds each nrlib name to *monitor-domains* but does not
;;; trace the functions from those domains
;;; monitor-percent () FUNCTION
;;; ratio of (functions executed)/(functions traced)
;;; monitor-apropos (str) FUNCTION
;;; given a string, find all monitored symbols containing the string
;;; the search is case-insensitive. returns a list of monitor-data items
") nil)

Chapter 76

The Global Variables

76.1 Star Global Variables

NAME	SET	USE
eof*	ncTopLevel	
features*		restart
package*		restart
standard-input*		ncIntLoop
standard-output*		ncIntLoop
top-level-hook*	set-restart-hook	

76.1.1 *eof*

The ***eof*** variable is set to NIL in ncTopLevel.

76.1.2 *features*

The ***features*** variable from common lisp is tested for the presence of the **:unix** keyword. Apparently this controls the use of Saturn, a previous Axiom frontend. The Saturn frontend was never released as open source and so this test and the associated variables are probably not used.

76.1.3 *package*

The ***package*** variable, from common lisp, is set in restart to the BOOT package where the interpreter lives.

76.1.4 ***standard-input***

The ***standard-input*** common lisp variable is used to set the `curinstream` variable in `ncIntLoop`.

This variable is an argument to `serverReadLine` in the `intloopReadConsole` function.

76.1.5 ***standard-output***

The ***standard-output*** common lisp variable is used to set the `curoutstream` variable in `ncIntLoop`.

76.1.6 ***top-level-hook***

The ***top-level-hook*** common lisp variable contains the name of a function to invoke when an image is started. In our case it is called `restart`. This is the entry point to the Axiom interpreter.

76.2 Dollar Global Variables

NAME	SET	USE
\$boot	ncTopLevel	
coerceFailure		runspad
curinstream	ncIntLoop	
curoutstream	ncIntLoop	
\$currentLine	restart	removeUndoLines
\$dalymode		intloopReadConsole
\$displayStartMsgs		restart
\$e	ncTopLevel	
\$erMsgToss	SpadInterpretStream	
\$fn	SpadInterpretStream	
\$frameRecord	initvars	
	clearFrame	
	undoSteps	undoSteps
	recordFrame	recordFrame
\$HiFiAccess	initHist	historySpad2Cmd
	historySpad2Cmd	
		setHistoryCore
\$HistList	initHist	
\$HistListAct	initHist	
\$HistListLen	initHistList	
\$HistRecord	initHistList	
\$historyDirectory		makeHistFileName
		makeHistFileName
\$historyFileType	initvars	histInputFileName
\$InteractiveFrame	restart	ncTopLevel
	undo	recordFrame
	undoSteps	undoSteps
		reportUndo
\$internalHistoryTable	initvars	
\$interpreterFrameName	initializeInterpreterFrameRing	
\$interpreterFrameRing	initializeInterpreterFrameRing	
\$intRestart		intloop
\$intTopLevel	intloop	
\$IOindex	restart	historySpad2Cmd
	removeUndoLines	undoCount
\$genValue	bookvol5	i-toplev
		i-analy
		i-syscmd
		i-spec1
		i-spec2
		i-map
\$lastPos	SpadInterpretStream	
\$libQuiet	SpadInterpretStream	
\$msgDatabaseName	reroot *	
\$ncMsgList	SpadInterpretStream	
\$newcompErrorCount	SpadInterpretStream	
\$newspad	ncTopLevel	
\$nupos		SpadInterpretStream
\$okToExecuteMachineCode	SpadInterpretStream	
\$oldHistoryFileName	initvars	oldHistFileName
\$options		history
	historySpad2Cmd	historySpad2Cmd
		undo

76.2.1 \$boot

The `$boot` variable is set to `NIL` in `ncTopLevel`.

76.2.2 coerceFailure

The `coerceFailure` symbol is a catch tag used in `runspad` to catch an exit from `ncTopLevel`.

76.2.3 \$currentLine

The `$currentLine` line is set to `NIL` in `restart`. It is used in `removeUndoLines` in the undo mechanism.

76.2.4 \$displayStartMsgs

The `$displayStartMsgs` variable is used in `restart` but is not set so this is likely a bug.

76.2.5 \$e

The `$e` variable is set to the value of `$InteractiveFrame` which is set in `restart` to the value of the call to the `makeInitialModemapFrame` function. This function simply returns a copy of the variable `$InitialModemapFrame`.

Thus `$e` is a copy of the variable `$InitialModemapFrame`.

This variable is used in the undo mechanism.

76.2.6 \$erMsgToss

The `$erMsgToss` variable is set to `NIL` in `SpadInterpretStream`.

76.2.7 \$fn

The `$fn` variable is set in `SpadInterpretStream`. It is set to the second argument which is a list. It appears that this list has the same structure as an argument to the `LispVM rdefiostream` function.

76.2.8 \$frameRecord

`$frameRecord = [delta1, delta2, ...]` where `delta(i)` contains changes in the “backwards” direction. Each `delta(i)` has the form `((var . proplist)...)` where `proplist` denotes an ordinary `proplist`. For example, an entry of the form `((x (value) (mode (Integer))))` indicates that to undo 1 step, `x`’s value is cleared and its mode should be set to `(Integer)`.

A `delta(i)` of the form `(systemCommand . delta)` is a special delta indicating changes due to system commands executed between the last command and the current command. By recording these deltas separately, it is possible to undo to either BEFORE or AFTER the command. These special `delta(i)`s are given ONLY when a system command is given which alters the environment.

Note: `recordFrame('system)` is called before a command is executed, and `recordFrame('normal)` is called after (see `processInteractive1`). If no changes are found for former, no special entry is given.

This is part of the undo mechanism.

76.2.9 \$HiFiAccess

The `$HiFiAccess` is set by `initHist` to T. It is a flag used by the history mechanism to record whether the history function is currently on. It can be reset by using the axiom command

```
)history off
```

It appears that the name means “History File Access”.

The `$HiFiAccess` variable is used by `historySpad2Cmd` to check whether history is turned on. T means it is, NIL means it is not.

76.2.10 \$HistList

This `$HistList` variable is set by `initHistList` to an initial value of NIL elements. The last element of the list is smashed to point to the first element to make the list circular. This is a circular list of length `$HistListLen`.

76.2.11 \$HistListAct

The `$HistListAct` variable is set by `initHistList` to 0. This variable holds the actual number of elements in the history list. This is the number of “undoable” steps.

76.2.12 \$HistListLen

The `$HistListLen` variable is set by `initHistList` to 20. This is the length of a circular list maintained in the variable `$HistList`.

76.2.13 \$HistRecord

The `$HistRecord` variable is set by `initHistList` to NIL. `$HistRecord` collects the input line, all variable bindings and the output of a step, before it is written to the file named by the function `histFileName`.

76.2.14 `$historyFileType`

The `$historyFileType` is set at load time by a call to `initvars` to a value of “axh”. It appears that this is intended to be used as a filetype extension. It is part of the history mechanism. It is used in `makeHistFileName` as part of the history file name.

76.2.15 `$internalHistoryTable`

The `$internalHistoryTable` variable is set at load time by a call to `initvars` to a value of `NIL`. It is part of the history mechanism.

76.2.16 `$interpreterFrameName`

The `$interpreterFrameName` variable, set in `initializeInterpreterFrameRing` to the constant `initial` to indicate that this is the initial (default) frame.

Frames are structures that capture all of the variables defined in a session. There can be multiple frames and the user can freely switch between them. Frames are kept in a ring data structure so you can move around the ring.

76.2.17 `$interpreterFrameRing`

The `$interpreterFrameRing` is set to a pair whose `car` is set to the result of `emptyInterpreterFrame`

76.2.18 `$InteractiveFrame`

The `$InteractiveFrame` is set in `restart` to the value of the call to the `makeInitialModemapFrame` function. This function simply returns a copy of the variable `$InitialModemapFrame`

76.2.19 `$intRestart`

The `$intRestart` variable is used in `intloop` but has no value. This is probably a bug. While the variable’s value is unchanged the system will continually reenter the `SpadInterpretStream` function.

76.2.20 `$intTopLevel`

The `$intTopLevel` is a catch tag. Throwing to this tags which is caught in the `intloop` will restart the `SpadInterpretStream` function.

76.2.21 `$IOindex`

The `$IOindex` index variable is set to 1 in restart. This variable is used in the `historySpad2Cmd` function in the history mechanism. It is set in the `removeUndoLines` function in the undo mechanism.

This is used in the undo mechanism in function `undoCount` to compute the number of undos. You can't undo more actions than have already happened.

76.2.22 `$lastPos`

The `$lastPos` variable is set in `SpadInterpretStream` to the value of the `$nopus` variable. Since `$nopus` appears to have no value this is likely a bug.

76.2.23 `$libQuiet`

The `$libQuiet` variable is set to the third argument of the `SpadInterpretStream` function. This is passed from `intloop` with the value of T. This variable appears to be intended to control the printing of library loading messages which would need to be suppressed if input was coming from a file.

76.2.24 `$msgDatabaseName`

The `$msgDatabaseName` is set to NIL in `reroot`.

76.2.25 `$ncMsgList`

The `$ncMsgList` is set to NIL in `SpadInterpretStream`.

76.2.26 `$newcompErrorCount`

The `$newcompErrorCount` is set to 0 in `SpadInterpretStream`.

76.2.27 `$newspad`

The `$newspad` is set to T in `ncTopLevel`.

76.2.28 `$nopus`

The `$nopus` variable is used in `SpadInterpretStream` but does not appear to have a value and is likely a bug.

76.2.29 \$oldHistoryFileName

The `$oldHistoryFileName` is set at load time by a call to `initvars` to a value of “last”. It is part of the history mechanism. It is used in the function `oldHistFileName` and `restoreHistory`.

76.2.30 \$okToExecuteMachineCode

The `$okToExecuteMachineCode` is set to T in `SpadInterpretStream`.

76.2.31 \$options

The `$options` variable is tested by the history function. If it is NIL then output the message

```
You have not used the correct syntax for the history command.  
Issue )help history for more information.
```

The `$options` variable is tested in the `historySpad2Cmd` function. It appears to record the options that were given to a `spad` command on the input line. The function `selectOptionLC` appears to take a list off options to scan.

This variable is not yet set and is probably a bug.

76.2.32 \$previousBindings

The `$previousBindings` is a copy of the `CAAR $InteractiveFrame`. This is used to compute the `delta(i)s` stored in `$frameRecord`. This is part of the undo mechanism.

76.2.33 \$PrintCompilerMessageIfTrue

The `$PrintCompilerMessageIfTrue` variable is set to NIL in `spad`.

76.2.34 \$reportUndo

The `$reportUndo` variable is used in `diffAlist`. It was not normally bound but has been set to T in `initvars`. If the variable is set to T then we call `reportUndo`.

It is part of the undo mechanism.

76.2.35 \$spad

The `$spad` variable is set to T in `ncTopLevel`.

76.2.36 `$SpadServer`

If an open server is not requested then this variable is T. It has no value before this time (and is thus a bug).

76.2.37 `$SpadServerName`

The `$SpadServerName` is passed to the `openServer` function, if the function exists.

76.2.38 `$systemCommandFunction`

The `$systemCommandFunction` is set in `SpadInterpretStream` to point to the function `InterpExecuteSpadSystemCommand`.

76.2.39 `top_level`

The `top_level` symbol is a catch tag used in `runspad` to catch an exit from `ncTopLevel`.

76.2.40 `$quitTag`

The `$quitTag` is used as a variable in a catch block. It appears that it can be thrown somewhere below `ncTopLevel`.

76.2.41 `$useInternalHistoryTable`

The `$useInternalHistoryTable` variable is set at load time by a call to `initvars` to a value of `NIL`. It is part of the history mechanism.

76.2.42 `$undoFlag`

The `$undoFlag` is used in `recordFrame` to decide whether to do undo recording. It is initially set to T in `initvars`. This is part of the undo mechanism.
