3.100 sregset.ht

3.100.1 SquareFreeRegularTriangularSet

```

\begin{page}{SqFreeRegTriangSetXmpPage}
\begin{SquareFreeRegularTriangularSet}
\begin{scroll}

```

The `\spadtype{SquareFreeRegularTriangularSet}` domain constructor implements square-free regular triangular sets. See the `\spadtype{RegularTriangularSet}` domain constructor for general regular triangular sets. Let $\{T\}$ be a regular triangular set consisting of polynomials $\{t_1, \dots, t_m\}$ ordered by increasing main variables. The regular triangular set $\{T\}$ is square-free if $\{T\}$ is empty or if $\{t_1, \dots, t_{m-1}\}$ is square-free and if the polynomial t_m is square-free as a univariate polynomial with coefficients in the tower of simple extensions associated with $\{t_1, \dots, t_{m-1}\}$.

The main interest of square-free regular triangular sets is that their associated towers of simple extensions are product of fields. Consequently, the saturated ideal of a square-free regular triangular set is radical. This property simplifies some of the operations related to regular triangular sets. However, building square-free regular triangular sets is generally more expensive than building general regular triangular sets.

As the `\spadtype{RegularTriangularSet}` domain constructor, the `\spadtype{SquareFreeRegularTriangularSet}` domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the `\spadtype{LazardSetSolvingPackage}` package constructor.

N.B. When solving polynomial systems with the `\spadtype{SquareFreeRegularTriangularSet}` domain constructor or the `\spadtype{LazardSetSolvingPackage}` package constructor, decompositions have no redundant components. See also `\spadtype{LexTriangularPackage}` and `\spadtype{ZeroDimensionalSolvePackage}` for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor
`\spadtype{SquareFreeRegularTriangularSet}`.

This constructor takes four arguments. The first one, `{\bf R}`, is the coefficient ring of the polynomials; it must belong to the category `\spadtype{GcdDomain}`. The second one, `{\bf E}`, is the exponent monoid of the polynomials; it must belong to the category `\spadtype{OrderedAbelianMonoidSup}`. the third one, `{\bf V}`, is the ordered set of variables; it must belong to the category `\spadtype{OrderedSet}`. The last one is the polynomial ring; it must belong to the category `\spadtype{RecursivePolynomialCategory(R,E,V)}`. The abbreviation for `\spadtype{SquareFreeRegularTriangularSet}` is `\spadtype{SREGSET}`.

Note that the way of understanding triangular decompositions is detailed in the example of the `\spadtype{RegularTriangularSet}` constructor.

```
\xctc{
Let us illustrate the use of this constructor
with one example (Donati-Traverso).
Define the coefficient ring.
}{
\spadpaste{R := Integer \bound{R}}
}
\xctc{
Define the list of variables,
}{
\spadpaste{ls : List Symbol := [x,y,z,t] \bound{ls}}
}
\xctc{
and make it an ordered set;
}{
\spadpaste{V := OVAR(ls) \free{ls} \bound{V}}
}
\xctc{
then define the exponent monoid.
}{
\spadpaste{E := IndexedExponents V \free{V} \bound{E}}
}
\xctc{
Define the polynomial ring.
}{
\spadpaste{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
}
\xctc{
```

```

Let the variables be polynomial.
}{
\spadpaste{x: P := 'x \free{P} \bound{x}}
}
\xtc{
}{
\spadpaste{y: P := 'y \free{P} \bound{y}}
}
\xtc{
}{
\spadpaste{z: P := 'z \free{P} \bound{z}}
}
\xtc{
}{
\spadpaste{t: P := 't \free{P} \bound{t}}
}
\xtc{
Now call the \spadtype{SquareFreeRegularTriangularSet} domain
constructor.
}{
\spadpaste{ST := SREGSET(R,E,V,P) \free{R} \free{E} \free{V}
\free{P} \bound{ST} }
}
\xtc{
Define a polynomial system.
}{
\spadpaste{p1 := x ** 31 - x ** 6 - x - y \free{x} \free{y}
\bound{p1}}
}
\xtc{
}{
\spadpaste{p2 := x ** 8 - z \free{x} \free{z} \bound{p2}}
}
\xtc{
}{
\spadpaste{p3 := x ** 10 - t \free{x} \free{t} \bound{p3}}
}
\xtc{
}{
\spadpaste{lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3}
\bound{lp}}
}

\xtc{
First of all, let us solve this system in the sense of Kalkbrener.
}{

```

```

\spadpaste{zeroSetSplit(lp)$ST \free{lp} \free{ST}}
}
\xtc{
And now in the sense of Lazard (or Wu and other authors).
}{
\spadpaste{zeroSetSplit(lp,false)$ST \free{lp} \free{ST}
\bound{lts}}
}

```

Now to see the difference with the `\spadtype{RegularTriangularSet}` domain constructor,

```

\xtc{
we define:
}{
\spadpaste{T := REGSET(R,E,V,P) \free{R} \free{E} \free{V}
\free{P} \bound{T} }
}
\xtc{
and compute:
}{
\spadpaste{lts := zeroSetSplit(lp,false)$T \free{lp}
\free{T} \bound{lts}}
}

```

If you look at the second set in both decompositions in the sense of Lazard, you will see that the polynomial with main variable `{\bf y}` is not the same.

Let us understand what has happened.

```

\xtc{
We define:
}{
\spadpaste{ts := lts.2 \free{lts} \bound{ts}}
}
\xtc{
}{
\spadpaste{pol := select(ts,'y)$T \free{ts} \free{y} \free{T} \bound{pol}}
}
\xtc{
}{
\spadpaste{tower := collectUnder(ts,'y)$T \free{ts} \free{y}
\free{T} \bound{tower}}
}
\xtc{
}{
\spadpaste{pack := RegularTriangularSetGcdPackage(R,E,V,P,T)

```

```

\free{R} \free{E} \free{V} \free{P} \free{T} \bound{pack}}
}
\xtc{
Then we compute:
}{
\spadpaste{toseSquareFreePart(pol,tower)$pack \free{pol}
\free{tower} \free{pack}}
}
\endscroll

$\langle stbl.ht \rangle \equiv$

```

\begin{page}{SparseTableXmpPage}{SparseTable}
\beginscroll
%
The \spadtype{SparseTable} domain provides a general purpose
table type with default entries.
\xtc{
Here we create a table to save strings under integer keys.
The value \spad{"Try again!"} is returned if no other value has been
stored for a key.
}{
\spadpaste{t: SparseTable(Integer, String, "Try again!") := table()
\bound{t}}
}
\xtc{
Entries can be stored in the table.
}{
\spadpaste{t.3 := "Number three" \free{t}\bound{t1}}
}
\xtc{
}{
\spadpaste{t.4 := "Number four" \free{t}\bound{t2}}
}
\xtc{
These values can be retrieved as usual, but if a look up fails
the default entry will be returned.
}{
\spadpaste{t.3 \free{t1}}
}
\xtc{
}{
\spadpaste{t.2 \free{t}}
}
\xtc{
To see which values are explicitly stored, the
\spadfunFrom{keys}{SparseTable} and \spadfunFrom{entries}{SparseTable}
functions can be used.
}{

```

```

\spadpaste{keys t \free{t1 t2}}
}
\xtc{
}{
\spadpaste{entries t \free{t1 t2}}
}
If a specific table representation
is required, the \spadtype{GeneralSparseTable} constructor should be
used. The domain \spadtype{SparseTable(K, E, dflt)} is equivalent to
\spadtype{GeneralSparseTable(K,E, Table(K,E), dflt)}.
For more information, see
\downlink{‘Table’}{TableXmpPage}\ignore{Table} and

<stream.ht>≡

```
\begin{page}{StreamXmpPage}{Stream}
\beginscroll
```

A `\spadtype{Stream}` object is represented as a list whose last element contains the wherewithal to create the next element, should it ever be required.

```
\xtc{
Let \spad{ints} be the infinite stream of non-negative integers.
}{
\spadpaste{ints := [i for i in 0..] \bound{ints}}
}
```

By default, ten stream elements are calculated.

This number may be changed to something else by the system command `\spadcmd{set streams calculate}`.

For the display purposes of this book, we have chosen a smaller value.

```
\xtc{
More generally, you can construct a stream by specifying its initial
value and a function which, when given an element, creates the next
element.
}{
\spadpaste{f : List INT -> List INT \bound{fdec}}
}
\xtc{
}{
\spadpaste{f x == [x.1 + x.2, x.1] \bound{f}\free{fdec}}
}
\xtc{
}{
\spadpaste{fibs := [i.2 for i in [generate(f,[1,1])]] \bound{fibs}\free{f}}
}
\xtc{
You can create the stream of odd non-negative integers by either
filtering them from the integers, or by evaluating an expression for
each integer.
}{
```

```

\spadpaste{[i for i in ints | odd? i] \free{ints}}
}
\xtc{
}{
\spadpaste{odds := [2*i+1 for i in ints]\bound{odds}\free{ints}}
}
\xtc{
You can accumulate the initial segments of a stream using the
\spadfunFrom{scan}{StreamFunctions2} operation.
}{
\spadpaste{scan(0,+,odds) \free{odds}}
}
\xtc{
The corresponding elements of
two or more streams can be combined in this way.
}{
\spadpaste{[i*j for i in ints for j in odds]\free{ints} \free{odds}}
}
\xtc{
}{
\spadpaste{map(*,ints,odds)\free{ints odds}}
}
\xtc{
Many operations similar to those applicable to lists are available for
streams.
}{
\spadpaste{first ints \free{ints}}
}
\xtc{
}{
\spadpaste{rest ints \free{ints}}
}
\xtc{
}{
\spadpaste{fibs 20 \free{fibs}}
}
The packages \spadtype{StreamFunctions1},
\spadtype{StreamFunctions2} and
\spadtype{StreamFunctions3} export some useful stream manipulation
operations.

⇒ “notitle” (CharacterXmpPage) 3.15.1 on page 220

⇒ “notitle” (CharacterClassXmpPage) 3.14.1 on page 212

<string.ht>≡

```
\begin{page}{StringXmpPage}{String}
\beginscroll
```

The type `\spadtype{String}` provides character strings. Character strings provide all the operations for a one-dimensional array of characters, plus additional operations for manipulating text. For more information on related topics, see

`\downlink{‘Character’}{CharacterXmpPage}\ignore{Character}` and
`\downlink{‘CharacterClass’}{CharacterClassXmpPage}\ignore{CharacterClass}`.
 You can also issue the system command `\spadcmd{}show String` to display the full list of operations defined by `\spadtype{String}`.

```
\xctc{
String values can be created using double quotes.
}{
\spadpaste{hello := "Hello, I'm Axiom!" \bound{hello}}
}
\xctc{
Note, however, that double quotes and underscores must be preceded by
an extra underscore.
}{
\spadpaste{said := "Jane said, _"Look!_" \bound{said}}
}
\xctc{
}{
\spadpaste{saw := "She saw exactly one underscore: __." \bound{saw}}
}
\xctc{
It is also possible to use \spadfunFrom{new}{String} to create a
string of any size filled with a given character. Since there are
many \spadfun{new} functions it is necessary to indicate the desired
type.
}{
\spadpaste{gasp: String := new(32, char "x") \bound{gasp}}
}
\xctc{
The length of a string is given by \spadopFrom{\#}{List}.
```

```

}{
\spadpaste{\#gasp \free{gasp}}
}
\xtc{
Indexing operations allow characters to be extracted or replaced in
strings. For any string \spad{s},
indices lie in the range \spad{1..\#s}.
}{
\spadpaste{hello.2 \free{hello}}
}
\xtc{
Indexing is really just the application of a string to a subscript,
so any application syntax works.
}{
\spadpaste{hello 2 \free{hello}}
}
\xtc{
}{
\spadpaste{hello(2) \free{hello}}
}
\xtc{
If it is important not to modify a given string, it should be copied
before any updating operations are used.
}{
\spadpaste{hullo := copy hello \free{hello}\bound{hullo0}}
}
\xtc{
}{
\spadpaste{hullo.2 := char "u"; [hello, hullo] \free{hullo0 hello}
\bound{hullo}}
}

\xtc{
Operations are provided to split and join strings.
The \spadfunFrom{concat}{String} operation allows several strings
to be joined together.
}{
\spadpaste{said saw := concat ["alpha","---","omega"] \bound{said saw}}
}
\xtc{
There is a version of \spadfunFrom{concat}{String} that works with
two strings.
}{
\spadpaste{concat("hello ","goodbye")}
}
\xtc{

```

Juxtaposition can also be used to concatenate strings.

```
{
\spadpaste{"This " "is " "several " "strings " "concatenated."}
}
```

```
\xtc{
```

Substrings are obtained by giving an index range.

```
{
\spadpaste{hello(1..5) \free{hello}}
}
```

```
\xtc{
```

```
{
```

```
\spadpaste{hello(8..) \free{hello}}
}
```

```
\xtc{
```

A string can be split into several substrings by giving a separation character or character class.

```
{
\spadpaste{split(hello, char " ") \free{hello}}
}
```

```
\xtc{
```

```
{
```

```
\spadpaste{other := complement alphanumeric(); \bound{other}}
}
```

```
\xtc{
```

```
{
```

```
\spadpaste{split(said saw, other) \free{said saw other}}
}
```

```
\xtc{
```

Unwanted characters can be trimmed from the beginning or end of a string using the operations `\spadfunFrom{trim}{String}`, `\spadfunFrom{leftTrim}{String}` and `\spadfunFrom{rightTrim}{String}`.

```
{
\spadpaste{trim ("#\# ++ relax ++ \#\#", char "\#")}
}
```

```
\xtc{
```

Each of these functions takes a string and a second argument to specify the characters to be discarded.

```
{
\spadpaste{trim ("#\# ++ relax ++ \#\#", other) \free{other}}
}
```

```
\xtc{
```

The second argument can be given either as a single character or as a character class.

```
{
\spadpaste{leftTrim ("#\# ++ relax ++ \#\#", other) \free{other}}
}
```

```

\xtc{
}{
\spadpaste{rightTrim("#\# ++ relax ++ \#", other) \free{other}}
}

\xtc{
Strings can be changed to upper case or lower case using the operations
\spadfunFrom{upperCase}{String}, \spadfunFromX{upperCase}{String},
\spadfunFrom{lowerCase}{String} and
\spadfunFromX{lowerCase}{String}.
}{
\spadpaste{upperCase hello \free{hello}}
}

\xtc{
The versions with the exclamation mark
change the original string, while the others produce a copy.
}{
\spadpaste{lowerCase hello \free{hello}}
}

\xtc{
Some basic string matching is provided.
The function \spadfunFrom{prefix?}{String}
tests whether one string is an initial prefix of another.
}{
\spadpaste{prefix?("He", "Hello")}
}

\xtc{
}{
\spadpaste{prefix?("Her", "Hello")}
}

\xtc{
A similar function, \spadfunFrom{suffix?}{String}, tests for suffixes.
}{
\spadpaste{suffix?("", "Hello")}
}

\xtc{
}{
\spadpaste{suffix?("LO", "Hello")}
}

\xtc{
The function \spadfunFrom{substring?}{String} tests for a substring
given a starting
position.
}{
\spadpaste{substring?("ll", "Hello", 3)}
}

```

```

}
\xtc{
}{
\spadpaste{substring?("ll", "Hello", 4)}
}

\xtc{
A number of \spadfunFrom{position}{String} functions locate things in
strings. If the first argument to position is a string, then
\spad{position(s,t,i)} finds the location of \spad{s} as a substring
of \spad{t} starting the search at position \spad{i}.
}{
\spadpaste{n := position("nd", "underground", 1) \bound{n}}
}
\xtc{
}{
\spadpaste{n := position("nd", "underground", n+1) \free{n} \bound{n1}}
}
\xtc{
If \spad{s} is not found, then \spad{0} is returned (\spad{minIndex(s)-1}
in \spadtype{IndexedString}).
}{
\spadpaste{n := position("nd", "underground", n+1) \free{n1}\bound{n2}}
}
\xtc{
To search for a specific character or a member of a character class,
a different first argument is used.
}{
\spadpaste{position(char "d", "underground", 1)}
}
\xtc{
}{
\spadpaste{position(hexDigit(), "underground", 1)}
}

3.105 symbol.ht

3.105.1 Symbol

(symbol.ht)≡

```
\begin{page}{SymbolXmpPage}{Symbol}
\beginscroll
```

Symbols are one of the basic types manipulated by Axiom.

The `\spadtype{Symbol}` domain provides ways to create symbols of many varieties.

```
\showBlurb{Symbol}
```

```
\xtc{
```

The simplest way to create a symbol is to ‘single quote’ an identifier.

```
}{
```

```
\spadpaste{X: Symbol := 'x \bound{X}}
```

```
}
```

```
\xtc{
```

This gives the symbol even if `\spad{x}` has been assigned a value.

If `\spad{x}` has not been assigned a value, then it is possible to omit the quote.

```
}{
```

```
\spadpaste{XX: Symbol := x}
```

```
}
```

```
\xtc{
```

Declarations must be used when working

with symbols, because otherwise the interpreter tries to place values in a more specialized type `\spadtype{Variable}`.

```
}{
```

```
\spadpaste{A := 'a}
```

```
}
```

```
\xtc{
```

```
}{
```

```
\spadpaste{B := b}
```

```
}
```

```
\xtc{
```

The normal way of entering polynomials uses this fact.

```
}{
```

```
\spadpaste{x**2 + 1}
```

```
}
```

```
\xtc{
```

Another convenient way to create symbols is to convert a string.

This is useful when the name is to be constructed by a program.

```
}{
```

```

\spadpaste{"Hello":Symbol}
}
\xtc{
Sometimes it is necessary to generate new unique symbols, for example, to
name constants of integration.
The expression \spad{new()} generates a symbol starting with \spad{\%}.
}{
\spadpaste{new()\$Symbol}
}
\xtc{
Successive calls to \spadfunFrom{new}{Symbol} produce different symbols.
}{
\spadpaste{new()\$Symbol}
}
\xtc{
The expression \spad{new("s")} produces a symbol starting with \spad{\%s}.
}{
\spadpaste{new("xyz")\$Symbol}
}

\xtc{
A symbol can be adorned in various ways.
The most basic thing is applying a symbol to a list
of subscripts.
}{
\spadpaste{X[i,j] \free{X}}
}

\xtc{
Somewhat less pretty is to attach subscripts, superscripts or arguments.
}{
\spadpaste{U := subscript(u, [1,2,1,2]) \bound{U}}
}
\xtc{
}{
\spadpaste{V := superscript(v, [n]) \bound{V}}
}
\xtc{
}{
\spadpaste{P := argscript(p, [t]) \bound{P}}
}

\xtc{
It is possible to test whether a symbol has scripts using the
\spadfunFrom{scripted?}{Symbol} test.
}{

```

```

\spadpaste{scripted? U \free{U}}
}
\xtc{
}{
\spadpaste{scripted? X \free{X}}
}
\xtc{
If a symbol is not scripted, then it may be converted to a string.
}{
\spadpaste{string X \free{X}}
}
\xtc{
The basic parts can always be extracted using the
\spadfunFrom{name}{Symbol} and \spadfunFrom{scripts}{Symbol} operations.
}{
\spadpaste{name U \free{U}}
}
\xtc{
}{
\spadpaste{scripts U \free{U}}
}
\xtc{
}{
\spadpaste{name X \free{X}}
}
\xtc{
}{
\spadpaste{scripts X \free{X}}
}

\xtc{
The most general form is obtained using the \spadfunFrom{script}{Symbol}
operation.
This operation takes an argument which is a list containing, in this order,
lists of subscripts, superscripts, presuperscripts, presubscripts and
arguments to a symbol.
}{
\spadpaste{M := script(Mammoth, [[i,j],[k,l],[0,1],[2],[u,v,w]])
\bound{M}}
}
\xtc{
}{
\spadpaste{scripts M \free{M}}
}
\xtc{
If trailing lists of scripts are omitted, they are assumed to be empty.

```

```

}{
\spadpaste{N := script(Nut, [[i,j],[k,l],[0,1]]) \bound{N}}
}
\xtc{
}{
\spadpaste{scripts N \free{N}}
}
\endscroll

 ⇒ “notitle” (KeyedAccessFileXmpPage) 3.57.1 on page 809

`<table.ht>≡`

```
\begin{page}{TableXmpPage}{Table}
\beginscroll
```

The `\spadtype{Table}` constructor provides a general structure for associative storage. This type provides hash tables in which data objects can be saved according to keys of any type. For a given table, specific types must be chosen for the keys and entries.

```
\xtc{
```

In this example the keys to the table are polynomials with integer coefficients.

The entries in the table are strings.

```
}{
```

```
\spadpaste{t: Table(Polynomial Integer, String) := table() \bound{t}}
}
```

```
\xtc{
```

To save an entry in the table, the `\spadfunFrom{setelt}{Table}` operation is used.

This can be called directly, giving the table a key and an entry.

```
}{
```

```
\spadpaste{setelt(t, x**2 - 1, "Easy to factor") \bound{p1}\free{t}}
}
```

```
\xtc{
```

Alternatively, you can use assignment syntax.

```
}{
```

```
\spadpaste{t(x**3 + 1) := "Harder to factor" \bound{p2}\free{p1}}
}
```

```
\xtc{
```

```
}{
```

```
\spadpaste{t(x) := "The easiest to factor" \bound{p3}\free{p2}}
}
```

```
\xtc{
```

Entries are retrieved from the table by calling the

`\spadfunFrom{elt}{Table}` operation.

```

}{
\spadpaste{elt(t, x) \free{p3}}
}
\xtc{
This operation is called when a table is ‘‘applied’’ to a key using
this or the following syntax.
}{
\spadpaste{t.x \free{p3}}
}
\xtc{
}{
\spadpaste{t x \free{p3}}
}
\xtc{
Parentheses are used only for grouping. They are needed if the key is
an infix expression.
}{
\spadpaste{t.(x**2 - 1) \free{p3}}
}
\xtc{
Note that the \spadfunFrom{elt}{Table} operation is used only when the
key is known to be in the table---otherwise an error is generated.
}{
\spadpaste{t (x**3 + 1) \free{p3}}
}

\xtc{
You can get a list of all the keys to a table using the
\spadfunFrom{keys}{Table} operation.
}{
\spadpaste{keys t \free{p3}}
}
\xtc{
If you wish to test whether a key is in a table, the
\spadfunFrom{search}{Table} operation is used.
This operation returns either an entry or \spad{"failed"}.
}{
\spadpaste{search(x, t) \free{p3}}
}
\xtc{
}{
\spadpaste{search(x**2, t) \free{p3}}
}
\xtc{
The return type is a union so the success of the search can be tested
using \spad{case}.

```

```

\spadkey{case}
}{
\spadpaste{search(x**2, t) case "failed" \free{p3}}
}
\xtc{
The \spadfunFromX{remove}{Table} operation is used to delete values from a
table.
}{
\spadpaste{remove!(x**2-1, t) \free{p3} \bound{p4}}
}
\xtc{
If an entry exists under the key, then it is returned. Otherwise
\spadfunFromX{remove}{Table} returns \spad{"failed"}.
}{
\spadpaste{remove!(x-1, t) \free{p4}\bound{p5}}
}

\xtc{
The number of key-entry pairs can be found using the
\spadfunFrom{#}{Table} operation.
}{
\spadpaste{\#t \free{p5}}
}
\xtc{
Just as \spadfunFrom{keys}{Table} returns a list of keys to the table, a
list of all the entries can be obtained using the
\spadfunFrom{members}{Table} operation.
}{
\spadpaste{members t \free{p5}}
}
\xtc{
A number of useful operations take functions and map them on to the
table to compute the result. Here we count the entries which
have \spad{"Hard"} as a prefix.
}{
\spadpaste{count(s: String +-> prefix?("Hard", s), t) \free{p5}}
}

```

Other table types are provided to support various needs.

```
\indent{4}
```

```
\beginitems
```

```
\item[-] \spadtype{AssociationList} gives a list with a table view.
This allows new entries to be appended onto the front of the list to
cover up old entries. This is useful when table entries need to be
stacked or when frequent list traversals are required. See
\downlink{'AssociationList'}{AssociationListXmpPage}
```

`\ignore{AssociationList}` for more information.

`\item[-] \spadtype{EqTable}` gives tables in which keys are considered equal only when they are in fact the same instance of a structure. See `\downlink{'EqTable'}{EqTableXmpPage}\ignore{EqTable}` for more information.

`\item[-] \spadtype{StringTable}` should be used when the keys are known to be strings. See `\downlink{'StringTable'}{StringTableXmpPage}\ignore{StringTable}` for more information.

`\item[-] \spadtype{SparseTable}` provides tables with default entries, so lookup never fails. The `\spadtype{GeneralSparseTable}` constructor can be used to make any table type behave this way. See `\downlink{'SparseTable'}{SparseTableXmpPage}\ignore{SparseTable}` for more information.

`\item[-] \spadtype{KeyedAccessFile}` allows values to be saved in a file, accessed as a table. See `\downlink{'KeyedAccessFile'}{KeyedAccessFileXmpPage}\ignore{KeyedAccessFile}` for more information.

\begin{page}{TextFileXmpPage}{TextFile}
\beginscroll
```

The domain `\spadtype{TextFile}` allows Axiom to read and write character data and exchange text with other programs.

This type behaves in Axiom much like a `\spadtype{File}` of strings, with additional operations to cause new lines.

We give an example of how to produce an upper case copy of a file.

```
\xtc{
This is the file from which we read the text.
}{
\spadpaste{f1: TextFile := open("/etc/group", "input") \bound{f1}}
}
\xtc{
This is the file to which we read the text.
}{
\spadpaste{f2: TextFile := open("/tmp/MOTD", "output") \bound{f2}}
}
\xtc{
Entire lines are handled using the \spadfunFromX{readLine}{TextFile} and
\spadfunFromX{writeLine}{TextFile} operations.
}{
\spadpaste{l := readLine! f1 \free{f1}\bound{l}}
}
\xtc{
}{
\spadpaste{writeLine!(f2, upperCase l) \free{f2 l}}
}
\xtc{
Use the
\spadfunFrom{endOfFile?}{TextFile} operation to check if you have
reached the end of the file.
}{
\begin{spadsrc}[\free{f1 f2}\bound{Copied}]
while not endOfFile? f1 repeat
  s := readLine! f1
```

```

        writeLine!(f2, upperCase s)
    \end{spadsrc}
}
\xtc{
The file \spad{f1} is exhausted and should be closed.
}{
\spadpaste{close! f1  \free{Copied}\bound{closed1}}
}

\xtc{
It is sometimes useful to write lines a bit at a time.
The \spadfunFromX{write}{TextFile} operation allows this.
}{
\spadpaste{write!(f2, "-The-")  \free{Copied}\bound{tthhee}}
}
\xtc{
}{
\spadpaste{write!(f2, "-End-")  \free{tthhee}\bound{eenndd}}
}
\xtc{
This ends the line.
This is done in a machine-dependent manner.
}{
\spadpaste{writeLine! f2          \free{eenndd}\bound{LastLine}}
}
\xtc{
}{
\spadpaste{close! f2              \free{LastLine}\bound{closed2}}
}
\noOutputXtc{
Finally, clean up.
}{
\spadpaste{)system rm /tmp/MOTD  \free{closed2}}
}

```

3.109 type.ht

3.109.1 Category Type

```

<type.ht>≡
\begin{page}{CategoryType}{Category {\em Type}}
\beginscroll
{\em Type} is a primitive category in Axiom,
one which is an ancestor of all Axiom categories.

{\em Type} is the root of Axiom's category hierarchy,
a category with no properties (exported operations
and attributes) of which all other categories are descendants.
Two important children of {\em Type} are
\spadtype{SetCategory}, the category of all algebraic domains,
and \spadtype{Aggregate}, the category of all data structures.
\endscroll

```

3.110 union.ht

the "union of {\em A} and {\em B}" as described below.
\indent{0}\newline\tab{2}{\em Description:}\indent{15}\tab{0}
{\em Union(a:A,b:B)} denotes the class of objects
which are either members of domain {\em A} or of domain {\em B}.
The symbols {\em a} and {\em b} are called "tags" and
are used to identify the two "branches"
of the union.
The {\em Union} constructor can take any number of arguments and
has an alternate form without {\em tags}.
This tagged {\em Union} type is necessary, for example, to disambiguate
two branches of a union where {\em A} and {\em B} denote the same type.
{\em Union} is a primitive domain of Axiom which cannot be
defined in the Axiom language.
\endscroll\end{page}

$\langle up.ht \rangle \equiv$

```
\begin{page}{UnivariatePolyXmpPage}{UnivariatePolynomial}
\beginscroll
```

The domain constructor `\spadtype{UnivariatePolynomial}`
 (abbreviated `\spadtype{UP}`)
 creates domains of univariate polynomials in a specified variable.
 For example, the domain
`\spadtype{UP(a1,POLY FRAC INT)}` provides polynomials in the single
 variable `\spad{a1}` whose coefficients are general polynomials with
 rational number coefficients.

```
\beginImportant
\noindent {\bf Restriction:}
\texht{\begin{quotation}\noindent}{\newline\indent{5}}
Axiom does not allow you to create types where
\spadtype{UnivariatePolynomial} is contained in the coefficient type of
\spadtype{Polynomial}. Therefore,
\spadtype{UP(x,POLY INT)} is legal but \spadtype{POLY UP(x,INT)} is not.
\texht{\end{quotation}}{\indent{0}}
\endImportant
```

```
\xhc{
\spadtype{UP(x,INT)} is the domain of polynomials in the single
variable \spad{x} with integer coefficients.
}{
\spadpaste{(p,q) : UP(x,INT) \bound{pdec}\bound{qdec}}
}
\xhc{
}{
\spadpaste{p := (3*x-1)**2 * (2*x + 8) \free{pdec}\bound{p}}
}
\xhc{
}{
```

```

\spadpaste{q := (1 - 6*x + 9*x**2)**2 \free{qdec}\bound{q}}
}
\xtc{
The usual arithmetic operations are available for univariate
polynomials.
}{
\spadpaste{p**2 + p*q \free{p q}}
}
\xtc{
The operation \spadfunFrom{leadingCoefficient}{UnivariatePolynomial}
extracts the coefficient of the term of highest degree.
}{
\spadpaste{leadingCoefficient p \free{p}}
}
\xtc{
The operation \spadfunFrom{degree}{UnivariatePolynomial} returns
the degree of the polynomial.
Since the polynomial has only one variable, the variable is not supplied
to operations like \spadfunFrom{degree}{UnivariatePolynomial}.
}{
\spadpaste{degree p \free{p}}
}
\xtc{
The reductum of the polynomial, the polynomial obtained by
subtracting the term of highest order, is returned by
\spadfunFrom{reductum}{UnivariatePolynomial}.
}{
\spadpaste{reductum p \free{p}}
}
\xtc{
The operation \spadfunFrom{gcd}{UnivariatePolynomial} computes the
greatest common divisor of two polynomials.
}{
\spadpaste{gcd(p,q) \free{p q}}
}
\xtc{
The operation \spadfunFrom{lcm}{UnivariatePolynomial} computes the
least common multiple.
}{
\spadpaste{lcm(p,q) \free{p q}}
}
\xtc{
The operation \spadfunFrom{resultant}{UnivariatePolynomial}
computes the resultant of two univariate polynomials.
In the case of \spad{p} and \spad{q}, the resultant is \spad{0} because they
share a common root.

```

```

}{
\spadpaste{resultant(p,q) \free{p q}}
}
\xtc{
To compute the derivative of a univariate polynomial with respect to its
variable, use \spadfunFrom{D}{UnivariatePolynomial}.
}{
\spadpaste{D p \free{p}}
}
\xtc{
Univariate polynomials can also be used as if they were functions.
To evaluate a univariate polynomial at some point, apply
the polynomial to the point.
}{
\spadpaste{p(2) \free{p}}
}
\xtc{
The same syntax is used for composing two univariate polynomials, i.e.
substituting one polynomial for the variable in another.
This substitutes \spad{q} for the variable in \spad{p}.
}{
\spadpaste{p(q) \free{p q}}
}
\xtc{
This substitutes \spad{p} for the variable in \spad{q}.
}{
\spadpaste{q(p) \free{p q}}
}
\xtc{
To obtain a list of coefficients of the polynomial, use
\spadfunFrom{coefficients}{UnivariatePolynomial}.
}{
\spadpaste{l := coefficients p \free{p}\bound{l}}
}
\xtc{
From this you can use \spadfunFrom{gcd}{UnivariatePolynomial}
and \spadfunFrom{reduce}{List}
to compute the content of the polynomial.
}{
\spadpaste{reduce(gcd,l) \free{l}}
}
\xtc{
Alternatively (and more easily),
you can just call \spadfunFrom{content}{UnivariatePolynomial}.
}{
\spadpaste{content p \free{p}}
}

```

```
}
```

Note that the operation `\spadfunFrom{coefficients}{UnivariatePolynomial}` omits the zero coefficients from the list.

Sometimes it is useful to convert a univariate polynomial to a vector whose `\eth{\spad{i}}` position contains the degree `\spad{i-1}` coefficient of the polynomial.

```
\xrc{
}{
\spadpaste{ux := (x**4+2*x+3)::UP(x,INT) \bound{ux}}
}
```

To get a complete vector of coefficients, use the operation `\spadfunFrom{vectorise}{UnivariatePolynomial}`, which takes a univariate polynomial and an integer denoting the length of the desired vector.

```
{
\spadpaste{vectorise(ux,5) \free{ux}}
}
```

It is common to want to do something to every term of a polynomial, creating a new polynomial in the process.

```
\xrc{
This is a function for iterating across the terms of a polynomial,
squaring each term.
```

```
{
\begin{spadsrc}[\bound{squareTerms}]
squareTerms(p) ==
  reduce(+,[t**2 for t in monomials p])
\end{spadsrc}
}
```

```
\xrc{
Recall what \spad{p} looked like.
```

```
{
\spadpaste{p \free{p}}
}
\xrc{
We can demonstrate \userfun{squareTerms} on \spad{p}.
}{
\spadpaste{squareTerms p \free{p}\free{squareTerms}}
}
```

When the coefficients of the univariate polynomial belong to a field,^{Footnote}For example, when the coefficients are rational numbers, as opposed to integers. The important property of a field is that non-zero elements can be divided and produce

```

another element. The quotient of the integers 2 and 3 is not
another integer.}
it is possible to compute quotients and remainders.
\xtc{
}{
\spadpaste{(r,s) : UP(a1,FRAC INT) \bound{rdec}\bound{sdec}}
}
\xtc{
}{
\spadpaste{r := a1**2 - 2/3 \free{rdec}\bound{r}}
}
\xtc{
}{
\spadpaste{s := a1 + 4 \free{sdec}\bound{s}}
}
\xtc{
When the coefficients are rational numbers or rational expressions, the
operation \spadfunFrom{quo}{UnivariatePolynomial} computes the quotient
of two polynomials.
}{
\spadpaste{r quo s \free{r s}}
}
\xtc{
The operation
\spadfunFrom{rem}{UnivariatePolynomial} computes the remainder.
}{
\spadpaste{r rem s \free{r s}}
}
\xtc{
The operation \spadfunFrom{divide}{UnivariatePolynomial} can be used to
return a record of both components.
}{
\spadpaste{d := divide(r, s) \free{r s}\bound{d}}
}
\xtc{
Now we check the arithmetic!
}{
\spadpaste{r - (d.quotient * s + d.remainder) \free{r s d}}
}
\xtc{
It is also possible to integrate univariate polynomials when the
coefficients belong to a field.
}{
\spadpaste{integrate r \free{r}}
}
\xtc{

```

```

}{
\spadpaste{integrate s \free{s}}
}

```

One application of univariate polynomials is to see expressions in terms of a specific variable.

```

%
\xtc{
We start with a polynomial in \spad{a1} whose coefficients
are quotients of polynomials in \spad{b1} and \spad{b2}.
}{
\spadpaste{t : UP(a1,FRAC POLY INT) \bound{tdec}}
}
\xtc{
Since in this case we are not talking about using multivariate
polynomials in only two variables, we use \spadtype{Polynomial}.
We also use \spadtype{Fraction} because we want fractions.
}{
\spadpaste{t := a1**2 - a1/b2 + (b1**2-b1)/(b2+3) \free{tdec}\bound{t}}
}
\xtc{
We push all the variables into a single quotient of polynomials.
}{
\spadpaste{u : FRAC POLY INT := t \bound{u}\free{t}}
}
\xtc{
Alternatively, we can view this as a polynomial in the variable
This is a {\it mode-directed} conversion: you indicate
as much of the structure as you care about and let Axiom
decide on the full type and how to do the transformation.
}{
\spadpaste{u :: UP(b1,?) \free{u}}
}

```

See [\downlink{'Polynomial Factorization'}{ugProblemFactorPage}](#) in Section 8.2\ignore{ugProblemFactor} for a discussion of the factorization facilities in Axiom for univariate polynomials. ```

3.113 oreup.ht

3.113.1 UnivariateSkewPolynomial

```

<oreup.ht>≡
\begin{page}{UnivariateSkewPolyXmpPage}{UnivariateSkewPolynomial}
\beginscroll

Skew or Ore polynomial rings provide a unified framework to
compute with differential and difference equations.
\newline
In the following, let  $A$  be an integral domain, equipped with two
endomorphisms  $\sigma$  and  $\delta$  where:
\blankline
\begin{items}
\item  $\sigma: A \rightarrow A$  is an injective ring endomorphism
\item  $\delta: A \rightarrow A$ , the pseudo-derivation with respect to
 $\sigma$ , is an additive endomorphism with
\blankline

$$\delta(ab) = \sigma(a)\delta(b) + \delta(a)b$$

\blankline
for all  $a, b$  in  $A$ 
\end{items}
\blankline
The skew polynomial ring
 $[\Delta; \sigma, \delta]$  is the ring of
polynomials in  $\delta$  with coefficients in  $A$ , with the
usual addition, while the product is given by
\blankline

$$\delta a = \sigma(a)\delta + \delta(a)$$
 for  $a$  in  $A$ 
\blankline
The two most important examples of skew polynomial rings are:
\blankline
 $K(x)[D, 1, \delta]$ 
\blankline
where  $1$  is the identity on  $K$  and  $\delta$  is
the usual derivative, is the ring of differential polynomials
\blankline
 $\text{subscriptIt}{K}{n} [E, n, n \rightarrow n+1, 0]$ 
\blankline
is the ring of linear recurrence operators with polynomial coefficients

\horizontalline
The UnivariateSkewPolynomialCategory (OREPCAT) provides a unified
framework for polynomial rings in a non-central indeterminate over
some coefficient ring  $R$ . The commutation relations between the

```

```

indeterminate x and the coefficient t is given by
\blankline
  x r = \sigma(r) x + \delta(r)
\blankline
where \sigma is a ring endomorphism of R
and \delta is a \sigma-derivation of R
which is an additive map from R to R such that
\blankline
  \delta(rs) = \sigma(r) \delta(s) + \delta(r) s
\blankline
In case \sigma is the identity map on R, a \sigma-derivation of R
is just called a derivation.
\blankline
We start with a linear ordinary differential operator. First, we
define the coefficient ring to be expressions in one variable x
with fractional coefficients:
\blankline
  F := EXPR(FRAC(INT))
\blankline
Define Dx to be a derivative d/dx:
\blankline
  Dx: F->F := f+>D(f,['x'])
\blankline
Define a skew polynomial ring over F with identity endomorphism as
\sigma and derivation d/dx as \delta:
\begin{verbatim}
  D0 := OREUP('d,F,1,Dx)
\end{verbatim}
\begin{verbatim}
  u:D0 := (operator 'u)(x)
\end{verbatim}
\begin{verbatim}
  d:D0 := 'd
\end{verbatim}
\begin{verbatim}
  a:D0:=u^3*d^3+u^2*d^2+u*d+1
          3 3      2 2
        u(x) d  + u(x) d  + u(x)d + 1
\end{verbatim}
\begin{verbatim}
  b:D0:=(u+1)*d^2+2*d
          2
        (u(x) + 1)d  + 2d
\end{verbatim}

```

```

\begin{verbatim}
r:=rightDivide(a,b)

          3      3      3      2
          - u(x) u (x) - u(x) + u(x)
          u(x)
[quotient= ----- d + -----,
          u(x) + 1          2
                        u(x) + 2u(x) + 1
          3      3
          2u(x) u (x) + 3u(x) + u(x)

remainder= ----- d + 1]
          2
          u(x) + 2u(x) + 1

\end{verbatim}
\begin{verbatim}
r.quotient

          3      3      3      2
          - u(x) u (x) - u(x) + u(x)
          u(x)
----- d + -----
          u(x) + 1          2
                        u(x) + 2u(x) + 1

\end{verbatim}
\begin{verbatim}
r.remainder

          3      3
          2u(x) u (x) + 3u(x) + u(x)

----- d + 1
          2
          u(x) + 2u(x) + 1
\end{verbatim}

\horizontalline

)clear all
\blankline
As a second example, we consider the so-called Weyl algebra.
\blankline
Define the coefficient ring to be an ordinary polynomial over integers

```

```

in one variable t
\blankline
\begin{verbatim}
  R := UP('t,INT)
\end{verbatim}
\blankline
Define a skew polynomial ring over R with identity map as
\sigma
and derivation d/dt as \delta.
The resulting algebra is then called a Weyl algebra:
\blankline
\begin{verbatim}
  W := OREUP('x,R,1,D)

  t:W := 't

  x:W := 'x
\end{verbatim}
\blankline
Let
\begin{verbatim}
  a:W:=(t-1)*x^4+(t^3+3*t+1)*x^2+2*t*x+t^3
          4      3      2      3
      (t - 1)x  + (t  + 3t + 1)x  + 2t x + t
\end{verbatim}
\begin{verbatim}
  b:W:=(6*t^4+2*t^2)*x^3+3*t^2*x^2
          4      2 3      2 2
      (6t  + 2t )x  + 3t x
\end{verbatim}
\blankline
Then
\begin{verbatim}
  a*b
          5      4      3      2 7      4      3      2      6
      (6t  - 6t  + 2t  - 2t )x  + (96t  - 93t  + 13t  - 16t)x
+
          7      5      4      3      2      5
      (6t  + 20t  + 6t  + 438t  - 406t  - 24)x
+
          6      5      4      3      2      4
      (48t  + 15t  + 152t  + 61t  + 603t  - 532t  - 36)x
+
          7      5      4      3      2      3

```

```

(6t  + 74t  + 60t  + 226t  + 116t  + 168t - 140)x
+
      5      3      2      2
(3t  + 6t  + 12t  + 18t + 6)x

a^3
      3      2      12      5      4      3      2      10
(t  - 3t  + 3t - 1)x  + (3t  - 6t  + 12t  - 15t  + 3t + 3)x
+
      3      2      9      7      6      5      4      3      2      8
(6t  - 12t  + 6t)x  + (3t  - 3t  + 21t  - 18t  + 24t  - 9t  - 15t - 3)x
+
      5      4      3      2      7
(12t  - 12t  + 36t  - 24t  - 12t)x
+
      9      7      6      5      4      3      2      6
(t  + 15t  - 3t  + 45t  + 6t  + 36t  + 15t  + 9t + 1)x
+
      7      5      3      2      5
(6t  + 48t  + 54t  + 36t  + 6t)x
+
      9      7      6      5      4      3      2      4
(3t  + 21t  + 3t  + 39t  + 18t  + 39t  + 12t )x
+
      7      5      4      3      3      9      7      6      5      2      7      9
(12t  + 36t  + 12t  + 8t )x  + (3t  + 9t  + 3t  + 12t )x  + 6t x + t
\end{verbatim}

\horizontalline
)clear all
\blankline
As a third example, we construct a difference operator algebra over
the ring of  $\text{EXPR}(\text{INT})$  by using an automorphism  $S$  defined by a
"shift" operation  $S:\text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT})$ 
\blankline
\begin{verbatim}
s(e)(n) = e(n+1)
\end{verbatim}
\blankline
and an  $S$ -derivation defined by  $DF:\text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT})$  as
\blankline
\begin{verbatim}
DF(e)(n) = e(n+1)-e(n)
\end{verbatim}
\blankline
Define  $S$  to be a "shift" operator, which acts on expressions with

```

```

the discrete variable n:
\blankline
\begin{verbatim}
  S:EXPR(INT)->EXPR(INT):=e+-->eval(e,[n],[n+1])
\end{verbatim}
\blankline
Define DF to be a "difference" operator, which acts on expressions
with a discrete variable n:
\blankline
\begin{verbatim}
  DF:EXPR(INT)->EXPR(INT):=e+-->eval(e,[n],[n+1])-e
\end{verbatim}
\blankline
Then define the difference operator algebra D0:
\blankline
\begin{verbatim}
  D0:=OREUP('D,EXPR(INT),morphism S,DF)

  u:=(operator 'u)[n]

  L:D0:='D+u

      D + u(n)

  L^2

      2          2
      D  + 2u(n)D + u(n)
\end{verbatim}

\horizontalline
)clear all
\blankline
As a fourth example, we construct a skew polynomial ring by using an
inner derivation \delta induced by a fixed y in R:
\blankline
\delta(r) = yr - ry
\blankline
First we should expose the constructor SquareMatrix so it is visible
in the interpreter:
\blankline
)set expose add constructor SquareMatrix
\blankline
Define R to be the square matrix with integer entries:
\blankline
\begin{verbatim}

```

```

R:=SQMATRIX(2,INT)

y:R:=matrix [[1,1],[0,1]]
      +1  1+
      |   |
      +0  1+
\end{verbatim}
\blankline
Define the inner derivative \delta:
\blankline
      delta:R->R:=r+>y*r-r*y
\blankline
Define S to be a skew polynomial determined by \sigma = 1
and \delta as an inner derivative:
\blankline
\begin{verbatim}
      S:=OREUP('x,R,1,delta)

x:S:='x

a:S:=matrix [[2,3],[1,1]]
      +2  3+
      |   |
      +1  1+

x^2*a
      +2  3+ 2   +2  - 2+   +0  - 2+
      |   |x  + |   |x  + |   |
      +1  1+   +0  - 2+   +0  0  +
\end{verbatim}
\endscroll
\autobuttons
\end{page}

```

```
<vector.ht>≡
\begin{page}{VectorXmpPage}{Vector}
\beginscroll
```

The `\spadtype{Vector}` domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the `\spadtype{OneDimensionalArray}` domain, except that when the components of a `\spadtype{Vector}` belong to a `\spadtype{Ring}`, arithmetic operations are provided. For more examples of operations that are defined for both `\spadtype{Vector}` and `\spadtype{OneDimensionalArray}`, see `\downlink{‘OneDimensionalArray’}{OneDimensionalArrayXmpPage}` `\ignore{OneDimensionalArray}`.

As with the `\spadtype{OneDimensionalArray}` domain, a `\spadtype{Vector}` can be created by calling the operation `\spadfunFrom{new}{Vector}`, its components can be accessed by calling the operations `\spadfunFrom{elt}{Vector}` and `\spadfunFrom{qelt}{Vector}`, and its components can be reset by calling the operations `\spadfunFrom{setelt}{Vector}` and `\spadfunFromX{qsetelt}{Vector}`.
`\xctc{ This creates a vector of integers of length \spad{5} all of whose components are \spad{12}. }{ \spadpaste{u : VECTOR INT := new(5,12) \bound{u}} } \xctc{ This is how you create a vector from a list of its components. }{ \spadpaste{v : VECTOR INT := vector([1,2,3,4,5]) \bound{v}} }`

```
\xctc{
Indexing for vectors begins at \spad{1}.
The last element has index equal to the length of the vector,
which is computed by \spadopFrom{\#}{Vector}.
}{
```

```

\spadpaste{\#(v) \free{v}}
}
\xtc{
This is the standard way to use \spadfunFrom{elt}{Vector} to extract an
element.
Functionally, it is the same as if you had typed \spad{elt(v,2)}.
}{
\spadpaste{v.2 \free{v}}
}
\xtc{
This is the standard way to use \spadfunFrom{setelt}{Vector} to change an
element.
It is the same as if you had typed \spad{setelt(v,3,99)}.
}{
\spadpaste{v.3 := 99 \free{v}\bound{vdelta}}
}
\xtc{
Now look at \spad{v} to see the change. You can use
\spadfunFrom{qelt}{Vector} and \spadfunFromX{qsetelt}{Vector} (instead
of \spadfunFrom{elt}{Vector} and \spadfunFrom{setelt}{Vector},
respectively) but {\it only} when you know that the index is within
the valid range.

3.116 wutset.ht

3.116.1 WuWenTsunTriangularSet

wutset.ht≡

```
\begin{page}{WuWenTsunTriangularSetXmpPage}{WuWenTsunTriangularSet}
\beginscroll
The \spadtype{WuWenTsunTriangularSet} domain constructor implements
the characteristic set method of Wu Wen Tsun. This algorithm computes
a list of triangular sets from a list of polynomials such that the
algebraic variety defined by the given list of polynomials decomposes
into the union of the regular-zero sets of the computed triangular
sets. The constructor takes four arguments. The first one, {\bf R},
is the coefficient ring of the polynomials; it must belong to the
category \spadtype{IntegralDomain}. The second one, {\bf E}, is the
exponent monoid of the polynomials; it must belong to the category
\spadtype{OrderedAbelianMonoidSup}. The third one, {\bf V}, is the
ordered set of variables; it must belong to the category
\spadtype{OrderedSet}. The last one is the polynomial ring; it must
belong to the category \spadtype{RecursivePolynomialCategory(R,E,V)}.
The abbreviation for \spadtype{WuWenTsunTriangularSet} is
\spadtype{WUTSET}.
```

Let us illustrate the facilities by an example.

```
\xctc{
Define the coefficient ring.
}{
\spadpaste{R := Integer \bound{R}}
}
\xctc{
Define the list of variables,
}{
\spadpaste{ls : List Symbol := [x,y,z,t] \bound{ls}}
}
\xctc{
and make it an ordered set;
}{
\spadpaste{V := OVAR(ls) \free{ls} \bound{V}}
}
\xctc{
then define the exponent monoid.
}{
\spadpaste{E := IndexedExponents V \free{V} \bound{E}}
}
\xctc{
```

```

Define the polynomial ring.
}{
\spadpaste{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
}
\xtc{
Let the variables be polynomial.
}{
\spadpaste{x: P := 'x \free{P} \bound{x}}
}
\xtc{
}{
\spadpaste{y: P := 'y \free{P} \bound{y}}
}
\xtc{
}{
\spadpaste{z: P := 'z \free{P} \bound{z}}
}
\xtc{
}{
\spadpaste{t: P := 't \free{P} \bound{t}}
}
\xtc{
Now call the \spadtype{WuWenTsunTriangularSet} domain constructor.
}{
\spadpaste{T := WUTSET(R,E,V,P) \free{R} \free{E} \free{V}
\free{P} \bound{T} }
}
\xtc{
Define a polynomial system.
}{
\spadpaste{p1 := x ** 31 - x ** 6 - x - y \free{x} \free{y} \bound{p1}}
}
\xtc{
}{
\spadpaste{p2 := x ** 8 - z \free{x} \free{z} \bound{p2}}
}
\xtc{
}{
\spadpaste{p3 := x ** 10 - t \free{x} \free{t} \bound{p3}}
}
\xtc{
}{
\spadpaste{lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3} \bound{lp}}
}
\xtc{
Compute a characteristic set of the system.

```

```

}{
\spadpaste{characteristicSet(lp)$T \free{lp} \free{T}}
}
\xtc{
Solve the system.
}{
\spadpaste{zeroSetSplit(lp)$T \free{lp} \free{T}}
}

```

The `\spadtype{RegularTriangularSet}` and `\spadtype{SquareFreeRegularTriangularSet}` domain constructors, and the `\spadtype{LazardSetSolvingPackage}`, `\spadtype{SquareFreeRegularTriangularSet}` and `\spadtype{ZeroDimensionalSolvePackage}` package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the `\spadtype{WUTSET}` constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the `\spadtype{RegularTriangularSet}` constructor.

3.119 xpoly.ht

3.119.1 XPolynomial

(xpoly.ht)≡
`\begin{page}{XPolynomialXmpPage}{XPolynomial}`
`\beginscroll`
 The `\spadtype{XPolynomial}` domain constructor implements
 multivariate polynomials
 whose set of variables is `\spadtype{Symbol}`.
 These variables do not commute.
 The only parameter of this constructor is
 the coefficient ring which may be non-commutative.
 However, coefficients and variables commute.
 The representation of the polynomials is recursive.
 The abbreviation for `\spadtype{XPolynomial}` is `\spadtype{XPOLY}`.

Other constructors like `\spadtype{XPolynomialRing}`,
`\spadtype{XRecursivePolynomial}`
`\spadtype{XDistributedPolynomial}`,
`\spadtype{LiePolynomial}` and
`\spadtype{XPBWPolynomial}`
 implement multivariate polynomials
 in non-commutative variables.

We illustrate now some of the facilities of the `\spadtype{XPOLY}`
 domain constructor.

```
\xtc{
Define a polynomial ring over the integers.
}{
\spadpaste{poly := XPolynomial(Integer) \bound{poly}}
}
```

```
\xtc{
Define a first polynomial,
}{
\spadpaste{pr: poly := 2*x + 3*y-5 \free{poly} \bound{pr}}
}
```

```
\xtc{
and a second one.
}{
\spadpaste{pr2: poly := pr*pr \free{poly} \bound{pr2}}
```

```

}

\xtc{
Rewrite {\bf pr} in a distributive way,
}{
\spadpaste{pd := expand pr \free{pr} \bound{pd}}
}

\xtc{
compute its square,
}{
\spadpaste{pd2 := pd*pd \free{pd} \bound{pd2}}
}

\xtc{
and checks that:
}{
\spadpaste{expand(pr2) - pd2 \free{pr2} \free{pd2}}
}

\xtc{
We define:
}{
\spadpaste{qr := pr**3 \free{pr} \bound{qr}}
}

\xtc{
and:
}{
\spadpaste{qd := pd**3 \free{pd} \bound{qd}}
}

\xtc{
We truncate {\bf qd} at degree {\bf 3}:
}{
\spadpaste{trunc(qd,2) \free{qd}}
}

\xtc{
The same for {\bf qr}:
}{
\spadpaste{trunc(qr,2) \free{qr}}
}

\xtc{

```

```

We define:
}{
\spadpaste{Word := OrderedFreeMonoid Symbol \bound{Word}}
}

\xtc{
and:
}{
\spadpaste{w: Word := x*y**2 \free{Word} \bound{w}}
}

\xtc{
The we can compute the right-quotient of {\bf qr} by {\bf r}:
}{
\spadpaste{rquo(qr,w) \free{qr} \free{w}}
}

\xtc{
and the shuffle-product of {\bf pr} by {\bf r}:
}{
\spadpaste{sh(pr,w::poly) \free{pr} \free{w}}
}
\endscroll

3.120 xpr.ht

3.120.1 XPolynomialRing

`<xpr.ht>`≡
`\begin{page}{XPolynomialRingXmpPage}{XPolynomialRing}`
`\beginscroll`
 The `\spadtype{XPolynomialRing}` domain constructor implements
 generalized polynomials with coefficients from an arbitrary `\spadtype{Ring}`
 (not necessarily commutative) and whose exponents are
 words from an arbitrary `\spadtype{OrderedMonoid}`
 (not necessarily commutative too).
 Thus these polynomials are (finite) linear combinations of words.

This constructor takes two arguments.
 The first one is a `\spadtype{Ring}`
 and the second is an `\spadtype{OrderedMonoid}`.
 The abbreviation for `\spadtype{XPolynomialRing}` is `\spadtype{XPR}`.

Other constructors like `\spadtype{XPolynomial}`,
`\spadtype{XRecursivePolynomial}`
`\spadtype{XDistributedPolynomial}`,
`\spadtype{LiePolynomial}` and
`\spadtype{XPBWPolynomial}`
 implement multivariate polynomials
 in non-commutative variables.

We illustrate now some of the facilities of the `\spadtype{XPR}` domain
 constructor.

```
\xtc{
Define the free ordered monoid generated by the symbols.
}{
\spadpaste{Word := OrderedFreeMonoid(Symbol) \bound{Word}}
}

\xtc{
Define the linear combinations of these words with integer coefficients.
}{
\spadpaste{poly:= XPR(Integer,Word) \free{Word} \bound{poly}}
}

\xtc{
Then we define a first element from {\bf poly}.
}{
```

```
\spadpaste{p:poly := 2 * x - 3 * y + 1 \free{poly} \bound{p}}
}
```

```
\xtc{
And a second one.
}{
\spadpaste{q:poly := 2 * x + 1 \free{poly} \bound{q}}
}
```

```
\xtc{
We compute their sum,
}{
\spadpaste{p + q \free{p}\free{q} }
}
```

```
\xtc{
their product,
}{
\spadpaste{p * q \free{p}\free{q} }
}
```

```
\xtc{
and see that variables do not commute.
}{
\spadpaste{(p + q)^2 - p^2 - q^2 - 2*p*q \free{p}\free{q} }
}
```

```
\xtc{
Now we define a ring of square matrices,
}{
\spadpaste{M := SquareMatrix(2,Fraction Integer) \bound{M}}
}
```

```
\xtc{
and the linear combinations of words with these matrices as coefficients.
}{
\spadpaste{poly1:= XPR(M,Word) \free{Word} \free{M} \bound{poly1}}
}
```

```
\xtc{
Define a first matrix,
}{
```

```

\spadpaste{m1:M := matrix [[i*j**2 for i in 1..2] for j in 1..2]
\free{M} \bound{m1}}
}

\xtc{
a second one,
}{
\spadpaste{m2:M := m1 - 5/4 \free{M} \free{m1} \bound{m2}}
}

\xtc{
and a third one.
}{
\spadpaste{m3: M := m2**2 \free{M} \free{m2} \bound{m3}}
}

\xtc{
Define a polynomial,
}{
\spadpaste{pm:poly1 := m1*x + m2*y + m3*z - 2/3 \free{poly1}
\free{m1} \free{m2} \free{m3} \bound{pm}}
}

\xtc{
a second one,
}{
\spadpaste{qm:poly1 := pm - m1*x \free{m1} \free{pm} \bound{qm}}
}

\xtc{
and the following power.
}{
\spadpaste{qm**3 \bound{qm}}
}

3.121 zdsolve.ht

3.121.1 ZeroDimensionalSolvePackage

`<zdsolve.ht>≡`

```
\begin{page}{ZeroDimSolvePkgXmpPage}{ZeroDimensionalSolvePackage}
\beginscroll
```

The `\spadtype{ZeroDimensionalSolvePackage}` package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides `\bf no` multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the `\axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePackage}` operation (by calling the `\spadtype{InternalRationalUnivariateRepresentationPackage}` package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the `\spadtype{RealClosure}` of the coefficient ring. They are computed by the `\axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage}` and `\axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage}` operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the `\spadtype{RealClosure}` constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the `\axiomOpFrom{zeroSetSplit}{RegularTriangularSet}` operation from the `\spadtype{REGSET}` domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the `\axiomOpFrom{zeroSetSplit}{LexTriangularPackage}` from `\spadtype{LEXTRIPK}`. To use this later strategy with the operations `\axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePackage}`, `\axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage}` and `\axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage}` one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the `\spadtype{RegularTriangularSet}`

constructor.

The `\spadtype{ZeroDimensionalSolvePackage}` constructor takes three arguments. The first one `{\bf R}` is the coefficient ring; it must belong to the categories `\spadtype{OrderedRing}`, `\spadtype{EuclideanDomain}`, `\spadtype{CharacteristicZero}` and `\spadtype{RealConstant}`. This means essentially that `{\bf R}` is `\spadtype{Integer}` or `\spadtype{Fraction(Integer)}`. The second argument `{\bf ls}` is the list of variables involved in the systems to solve. The third one MUST BE `{\bf concat(ls,s)}` where `{\bf s}` is an additional symbol used for the univariate representations. The abbreviation for `\spadtype{ZeroDimensionalSolvePackage}` is `\spadtype{ZDSOLVE}`.

We illustrate now how to use the constructor `\spadtype{ZDSOLVE}` by two examples: the `{\em Arnborg and Lazard}` system and the `{\em L-3}` system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the `\spadtype{LexTriangularPackage}` constructor.

```
\xtc{
Define the coefficient ring.
}{
\spadpaste{R := Integer \bound{R}}
}

\xtc{
Define the lists of variables:
}{
\spadpaste{ls : List Symbol := [x,y,z,t] \bound{ls}}
}

\xtc{
and:
}{
\spadpaste{ls2 : List Symbol := [x,y,z,t,new()$Symbol] \bound{ls2}}
}

\xtc{
Call the package:
}{
\spadpaste{pack := ZDSOLVE(R,ls,ls2) \free{ls} \free{ls2}
\free{R} \bound{pack}}
}

\xtc{
```

Define a polynomial system (Arnborg-Lazard)

```
{
\spadpaste{p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z +
x*y + x*z + y*z \bound{p1}}
}
\xtc{
}{
\spadpaste{p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z +
x*y*z + y*z + x + z \bound{p2}}
}
\xtc{
}{
\spadpaste{p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z +
x*y*z + x*z + z + 1 \bound{p3}}
}
\xtc{
}{
\spadpaste{lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3} \bound{lp}}
}
```

Note that these polynomials do not involve the variable $\{\textbf{t}\}$;
we will use it in the second example.

```
\xtc{
First compute a decomposition into regular chains
(i.e. regular triangular sets).
}{
\spadpaste{triangSolve(lp)$pack \free{lp} \free{pack}}
}
```

We can see easily from this decomposition (consisting of a single
regular chain) that the input system has 20 complex roots.

```
\xtc{
Then we compute a univariate representation of this regular chain.
}{
\spadpaste{univariateSolve(lp)$pack \free{lp} \free{pack}}
}
```

We see that the zeros of our regular chain are split into three
components. This is due to the use of univariate polynomial
factorization.

Each of these components consist of two parts. The first one is an
irreducible univariate polynomial $\{\textbf{p}(\textbf{t})\}$ which defines a simple
algebraic extension of the field of fractions of $\{\textbf{R}\}$. The second
one consists of multivariate polynomials $\{\textbf{pol1}(x, \textbf{A})\}$, $\{\textbf{pol2}(x, \textbf{A})\}$, $\{\textbf{pol3}(x, \textbf{A})\}$, $\{\textbf{pol4}(x, \textbf{A})\}$, $\{\textbf{pol5}(x, \textbf{A})\}$, $\{\textbf{pol6}(x, \textbf{A})\}$, $\{\textbf{pol7}(x, \textbf{A})\}$, $\{\textbf{pol8}(x, \textbf{A})\}$, $\{\textbf{pol9}(x, \textbf{A})\}$, $\{\textbf{pol10}(x, \textbf{A})\}$, $\{\textbf{pol11}(x, \textbf{A})\}$, $\{\textbf{pol12}(x, \textbf{A})\}$, $\{\textbf{pol13}(x, \textbf{A})\}$, $\{\textbf{pol14}(x, \textbf{A})\}$, $\{\textbf{pol15}(x, \textbf{A})\}$, $\{\textbf{pol16}(x, \textbf{A})\}$, $\{\textbf{pol17}(x, \textbf{A})\}$, $\{\textbf{pol18}(x, \textbf{A})\}$, $\{\textbf{pol19}(x, \textbf{A})\}$, $\{\textbf{pol20}(x, \textbf{A})\}$.

$\text{pol2}(y, \%A)$ and $\text{pol3}(z, \%A)$. Each of these polynomials involve two variables: one is an indeterminate $\{x\}$, $\{y\}$ or $\{z\}$ of the input system $\{lp\}$ and the other is $\{ \%A \}$ which represents any root of $\{p(?)\}$. Recall that this $\{ \%A \}$ is the last element of the third parameter of `\spadtype{ZDSOLVE}`. Thus any complex root $\{ ? \}$ of $\{p(?)\}$ leads to a solution of the input system $\{lp\}$ by replacing $\{ \%A \}$ by this $\{ ? \}$ in $\text{pol1}(x, \%A)$, $\text{pol2}(y, \%A)$ and $\text{pol3}(z, \%A)$. Note that the polynomials $\text{pol1}(x, \%A)$, $\text{pol2}(y, \%A)$ and $\text{pol3}(z, \%A)$ have degree one w.r.t. $\{x\}$, $\{y\}$ or $\{z\}$ respectively. This is always the case for all univariate representations. Hence the operation `\univariateSolve` replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the `\spadtype{LexTriangularPackage}` package constructor.

```
\xct{
We now compute the solutions with real coordinates:
}{
\spadpaste{lr := realSolve(lp)$pack \free{lp} \free{pack} \bound{lr}}
}
```

```
\xct{
The number of real solutions for the input system is:
}{
\spadpaste{\# lr \free{lr}}
}
```

Each of these real solutions is given by a list of elements in `\spadtype{RealClosure(R)}`. In these 8 lists, the first element is a value of $\{z\}$, the second of $\{y\}$ and the last of $\{x\}$. This is logical since by setting the list of variables of the package to $\{x, y, z, t\}$ we mean that the elimination ordering on the variables is $\{t < z < y < x\}$. Note that each system treated by the `\spadtype{ZDSOLVE}` package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

```
\xct{
We can approximate these real numbers as follows.
This computation takes between 30 sec. and 5 min, depending on your
machine.
}{
\spadpaste{[[approximate(r,1/1000000) for r in point] for point in lr]
\free{lr}}
```

```

}

\xtc{
We can also concentrate on the solutions with real (strictly)
positive coordinates:
}{
\spadpaste{lpr := positiveSolve(lp)$pack \free{lp} \free{pack} \bound{lpr}}
}

```

Thus we have checked that the input system has no solution with strictly positive coordinates.

```

\xtc{
Let us define another polynomial system ({\em L-3}).
}{
\spadpaste{f0 := x**3 + y + z + t- 1 \bound{f0}}
}
\xtc{
}{
\spadpaste{f1 := x + y**3 + z + t -1 \bound{f1}}
}
\xtc{
}{
\spadpaste{f2 := x + y + z**3 + t-1 \bound{f2}}
}
\xtc{
}{
\spadpaste{f3 := x + y + z + t**3 -1 \bound{f3}}
}
\xtc{
}{
\spadpaste{lf := [f0, f1, f2, f3] \free{f0} \free{f1} \free{f2}
\free{f3} \bound{lf}}
}
}

```

```

\xtc{
First compute a decomposition into regular chains
(i.e. regular triangular sets).
}{
\spadpaste{lts := triangSolve(lf)$pack \free{lf} \free{pack} \bound{lts}}
}

```

```

\xtc{

```

Then we compute a univariate representation.

```
{
\spadpaste{univariateSolve(lf)$pack \free{lf} \free{pack}}
}
```

Note that this computation is made from the input system $\{\mathbf{lf}\}$.

```
\xtc{
However it is possible to reuse a pre-computed regular chain as follows:
```

```
{
\spadpaste{ts := lts.1 \free{lts} \bound{ts}}
}
\xtc{
{
\spadpaste{univariateSolve(ts)$pack \free{ts} \free{pack}}
}
\xtc{
{
\spadpaste{realSolve(ts)$pack \free{ts} \free{pack}}
}
```

```
\xtc{
We compute now the full set of points with real coordinates:
{
\spadpaste{lpr2 := realSolve(lf)$pack \free{lf} \free{pack} \bound{lpr2}}
}
```

```
\xtc{
The number of real solutions for the input system is:
```

```
{
\spadpaste{\#lpr2 \free{lpr2}}
}
```

Another example of computation of real solutions illustrates the `\spadtype{LexTriangularPackage}` package constructor.

```
\xtc{
We concentrate now on the solutions with real (strictly) positive
coordinates:
```

```
{
\spadpaste{lpr2 := positiveSolve(lf)$pack \free{lf} \free{pack}
\bound{lpr2}}
}
```

```
\xtc{
Finally, we approximate the coordinates of this point with 20 exact
digits:
```

```

} {
\spadpaste{[approximate(r,1/10**21)::Float for r in lpr2.1] \free{lpr2}}
}

3.122 zlindep.ht

3.122.1 IntegerLinearDependence

`<zlindep.ht>≡`

```
\begin{page}{IntegerLinearDependenceXmpPage}{IntegerLinearDependence}
\beginscroll
```

The elements $\text{\texht{\$v_1, \dots, v_n}}\{\text{\spad{v1}, \dots, vn}\}$ of a module $\text{\spad{M}}$ over a ring $\text{\spad{R}}$ are said to be $\text{\it linearly dependent over \spad{R}}$ if there exist $\text{\texht{\$c_1, \dots, c_n}}\{\text{\spad{c1}, \dots, cn}\}$ in $\text{\spad{R}}$, not all $\text{\smath{0}}$, such that $\text{\texht{\$c_1 v_1 + \dots c_n v_n = 0}}\{\text{\spad{c1*v1 + \dots + cn*vn = 0}}\}$. If such $\text{\texht{\$c_i}}\{\text{\spad{ci}}\}$'s exist, they form what is called a $\text{\it linear dependence relation over \spad{R}}$ for the $\text{\texht{\$v_i}}\{\text{\spad{vi}}\}$'s.

The package `\spadtype{IntegerLinearDependence}` provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

```
%
\xtc{
Consider the domain of two by two square matrices with integer entries.
}{
\spadpaste{M := SQMATRIX(2,INT) \bound{M}}
}
%
%
\xtc{
Now create three such matrices.
}{
\spadpaste{m1: M := squareMatrix matrix [[1, 2], [0, -1]]
\free{M}\bound{m1}}
}
\xtc{
}{
\spadpaste{m2: M := squareMatrix matrix [[2, 3], [1, -2]]
\free{M}\bound{m2}}
}
\xtc{
}{
\spadpaste{m3: M := squareMatrix matrix [[3, 4], [2, -3]]
\free{M}\bound{m3}}
```

```

}
%
%
\xtc{
This tells you whether \spad{m1}, \spad{m2} and \spad{m3} are linearly
dependent over the integers.
}{
\spadpaste{linearlyDependentOverZ? vector [m1, m2, m3] \free{m1 m2 m3}}
}
%
%
\xtc{
Since they are linearly dependent, you can ask for the dependence
relation.
}{
\spadpaste{c := linearDependenceOverZ vector [m1, m2, m3]
\free{m1 m2 m3}\bound{c}}
}
%
%
\xtc{
This means that the following linear combination should be \spad{0}.
}{
\spadpaste{c.1 * m1 + c.2 * m2 + c.3 * m3 \free{c m1 m2 m3}}
}
%
When a given set of elements are linearly dependent over \spad{R}, this
also means that at least one of them can be rewritten as a linear
combination of the others with coefficients in the quotient field of
\spad{R}.
%
\xtc{
To express a given element in terms of other elements, use the operation
\spadfunFrom{solveLinearlyOverQ}{IntegerLinearDependence}.
}{
\spadpaste{solveLinearlyOverQ(vector [m1, m3], m2) \free{m1 m2 m3}}

5.0.4 New polynomial domains and algorithms

```

<ug00.ht>+≡
\begin{page}{ugTwoTwoPolynomialsPage}
{0.2. New polynomial domains and algorithms}
\beginscroll

```

Univariate polynomial factorisation over the integers has been enhanced by updates to the `\spadtype{GaloisGroupFactorizer}` type and friends from Frederic Lehobey (Frederic.Lehobey@lifl.fr, University of Lille I, France).

The package constructor `\spadtype{PseudoRemainderSequence}` provides efficient algorithms by Lionel Ducos (Lionel.Ducos@mathlabo.univ-poitiers.fr, University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

Based on this package, the domain constructor `\spadtype{NewSparseUnivariatePolynomial}` extends the constructor `\spadtype{SparseUnivariatePolynomial}`. In a similar way, the `\spadtype{NewSparseMultivariatePolynomial}` extends the constructor `\spadtype{SparseUnivariatePolynomial}`; it also provides some additional operations related to polynomial system solving by means of triangular sets.

Several domain constructors implement regular triangular sets (or regular chains). Among them `\spadtype{RegularTriangularSet}` and `\spadtype{SquareFreeRegularTriangularSet}`. They also implement an algorithm by Marc Moreno Maza (marc@nag.co.uk, NAG) for computing triangular decompositions of polynomial systems. This method is refined in the package `\spadtype{LazardSetSolvingPackage}` in order to produce decompositions by means of Lazard triangular sets. For the case of polynomial systems with finitely many solutions, these decompositions can also be computed by the package `\spadtype{LexTriangularPackage}`.

The domain constructor `\spadtype{RealClosure}` by Renaud Rioboo (Renaud.Rioboo@lip6.fr, University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers.

Based on triangular decompositions and the `\spadtype{RealClosure}`

constructor, the package `\spadtype{ZeroDimensionalSolvePackage}` provides operations for computing symbolically the real or complex roots of polynomial systems with finitely many solutions.

Polynomial arithmetic with non-commutative variables has been improved too by a contribution of Michel Petitot (Michel.Petitot@lifl.fr, University of Lille I, France). The domain constructors `\spadtype{XRecursivePolynomial}` and `\spadtype{XDistributedPolynomial}` provide recursive and distributed representations for these polynomials. They are the non-commutative equivalents for the `\spadtype{SparseMultivariatePolynomial}` and `\spadtype{DistributedMultivariatePoly}` constructors. The constructor `\spadtype{LiePolynomial}` implement Lie polynomials in the Lyndon basis. The constructor `\spadtype{XPBWPolynomial}` manage polynomials with non-commutative variables in the `\texht{Poincar\'}{Poincare\space{-1}}{Birkhoff-Witt}` basis from the Lyndon basis. This allows to compute in the Lie Group associated with a free nilpotent Lie algebra by using the `\spadtype{LieExponentials}` domain constructor.

```

5.0.7 Enhancements to the Lisp system

```

<ug00.ht>+≡
\begin{page}{ugTwoTwoCCLPage}{0.5. Enhancements to the Lisp system}
\beginscroll

```

In this version of Axiom, certain Library operations have been accelerated by converting their Lisp implementations into kernel operations implemented directly in C. Here is a list of the accelerated operations. The given names encode the abbreviated type the operation comes from, the name of the operation and, in the case of exported functions, an encoded signature and numerical index.

\begin{page}{ugIntroPage}{1. An Overview of Axiom}
```

```
\beginscroll
```

Welcome to the Axiom environment for interactive computation and

problem solving. Consider this chapter a brief, whirlwind tour of the Axiom world. We introduce you to Axiom's graphics and the Axiom language. Then we give a sampling of the large variety of facilities in the Axiom system, ranging from the various kinds of numbers, to data types (like lists, arrays, and sets) and mathematical objects (like matrices, integrals, and differential equations). We conclude with the discussion of system commands and an interactive "undo."

Before embarking on the tour, we need to brief those readers working interactively with Axiom on some details.

Others can skip right immediately to

`\downlink{"Typographic Conventions"}{ugIntroTypoPage}` in Section 1.2`\ignore{ugIntroTypo}`.

\ug01.ht)+≡
\begin{page}{ugIntroStartPage}{1.1. Starting Up and Winding Down}
\beginscroll

```

You need to know how to start the Axiom system and how to stop it. We assume that Axiom has been correctly installed on your machine (as described in another Axiom document).

To begin using Axiom, issue the command `\bf axiom` to the operating system shell. There is a brief pause, some start-up messages, and then one or more windows appear.

If you are not running Axiom under the X Window System, there is only one window (the console). At the lower left of the screen there is a prompt that looks like

```

\begin{verbatim}
(1) ->
\end{verbatim}

```

When you want to enter input to Axiom, you do so on the same line after the prompt. The ‘‘1’’ in ‘‘(1)’’ is the computation step number and is incremented after you enter Axiom statements. Note, however, that a system command such as `\spadsys{}clear all` may change the step number in other ways. We talk about step numbers more when we discuss system commands and the workspace history facility.

If you are running Axiom under the X Window System, there may be two windows: the console window (as just described) and the Hyperdoc main menu. Hyperdoc is a multiple-window hypertext system that lets you view Axiom documentation and examples on-line, execute Axiom expressions, and generate graphics. If you are in a graphical windowing environment, it is usually started automatically when Axiom begins. If it is not running, issue `\spadsys{}hd` to start it. We discuss the basics of Hyperdoc in `\downlink{‘‘Using Hyperdoc’’}{ugHyperPage}` in Chapter 3\ignore{ugHyper}.

To interrupt an Axiom computation, hold down the `\texht{\fbox{\bf Ctrl}}{\bf Ctrl}` (control) key and press `\texht{\fbox{\bf c}}{\bf c}`.

This brings you back to the Axiom prompt.

`\beginImportant`

To exit from Axiom, move to the console window, type `\spadsys{}quit` at the input prompt and press the `\texht{\fbox{\bf Enter}}` key. You will probably be prompted with the following message: `\centerline{{Please enter {\bf y} or {\bf yes} if you really want to leave the }} \centerline{{interactive environment and return to the operating system}}` You should respond `{\bf yes}`, for example, to exit Axiom.

`\endImportant`

We are purposely vague in describing exactly what your screen looks like or what messages Axiom displays. Axiom runs on a number of different machines, operating systems and window environments, and these differences all affect the physical look of the system. You can also change the way that Axiom behaves via `\spadgloss{system commands}` described later in this chapter and in

`\downlink{'Axiom System Commands'}{ugSysCmdPage}` in Appendix B

`\ignore{ugSysCmd}`. System commands are special commands, like `\spadcmd{}set`, that begin with a closing parenthesis and are used to change your environment. For example, you can set a system variable so that you are not prompted for confirmation when you want to leave Axiom.

6.0.10 Clef

⇐ “Computation of Galois Groups” (ugProblemGaloisPage) 12.0.186 on page 2600

`<ug01.ht>+≡`

```
\begin{page}{ugAvailCLEFPage}{1.1.1. \Clef{}}
\beginscroll
%
```

If you are using Axiom under the X Window System, the `\Clef{}` command line editor is probably available and installed. With this editor you can recall previous lines with the up and down arrow keys `\texht{(\fbox{\uparrow} and \fbox{\downarrow})}`. To move forward and backward on a line, use the right and left arrows `\texht{(\fbox{\rightarrow} and \fbox{\leftarrow})}`. You can use the `\texht{\fbox{\bf Insert}}` key to toggle insert mode on or off. When you are in insert mode, the cursor appears as a large block and if you type anything, the characters are inserted into the line without deleting the previous ones.

If you press the `\texht{\fbox{\bf Home}}` key, the cursor moves to the beginning of the line and if you press the `\texht{\fbox{\bf End}}` key, the cursor moves to the end of

the line. Pressing
`\texht{\fbox{\bf Ctrl}--\fbox{\bf End}}{\bf Ctrl-End}`
deletes all the text from the cursor to the end of the line.

`\Clef{}` also provides Axiom operation name completion for a limited set of operations. If you enter a few letters and then press the `\texht{\fbox{\bf Tab}}{\bf Tab}` key, `\Clef{}` tries to use those letters as the prefix of an Axiom operation name. If a name appears and it is not what you want, press `\texht{\fbox{\bf Tab}}{\bf Tab}` again to see another name.

You are ready to begin your journey into the world of Axiom.
Proceed to the first stop.

6.0.11 Typographic Conventions

```

<ug01.ht>+≡
\begin{page}{ugIntroTypoPage}{1.2. Typographic Conventions}
\beginscroll

In this book we have followed these typographical conventions:
\indent{4}
\beginitems
%
\item[-] Categories, domains and packages are displayed in
\texht{a sans-serif typeface:}{this font:}
\axiomType{Ring}, \axiomType{Integer},
\axiomType{DiophantineSolutionPackage}.
%
\item[-] Prefix operators, infix operators, and
punctuation symbols in the Axiom
language are displayed in the text like this:
\axiomOp{+}, \axiomSyntax{\$}, \axiomSyntax{+>}.
%
\item[-] Axiom expressions or expression fragments are displayed in
\texht{a mon\o\space typeface:}{this font:}
\axiom{inc(x) == x + 1}.
%
\item[-] For clarity of presentation, \TeX{} is often
used to format expressions\texht{: \$g(x)=x^2+1.\$}{.}
%
\item[-] Function names and Hyperdoc button names
are displayed in the text in
\texht{a bold typeface:}{this font:}
\axiomFun{factor}, \axiomFun{integrate}, {\bf Lighting}.
%
\item[-] Italics are used for emphasis and for words defined in the
glossary: \spadgloss{category}.
\enditems
\indent{0}

```

This book contains over 2500 examples of Axiom input and output. All examples were run through Axiom and their output was created in `\texht{\TeX{}}{\TeX{}}` form for this book by the Axiom `\axiomType{TexFormat}` package. We have deleted system messages from the example output if those messages are not important for the discussions in which the examples appear.

\beginscroll
%
```

The Axiom language is a rich language for performing interactive computations and for building components of the Axiom library. Here we present only some basic aspects of the language that you need to know for the rest of this chapter. Our discussion here is intentionally informal, with details unveiled on an ‘‘as needed’’ basis. For more information on a particular construct, we suggest you consult the index at the back of the book.

6.0.13 Arithmetic Expressions

<ug01.ht>+≡

```
\begin{page}{ugIntroArithmeticPage}{1.3.1. Arithmetic Expressions}
\beginscroll
```

For arithmetic expressions, use the `\spadop{+}` and `\spadop{-}` `\spadglossSee{operators}{operator}` as in mathematics. Use `\spadop{*}` for multiplication, and `\spadop{**}` for exponentiation. To create a fraction, use `\spadop{/}`. When an expression contains several operators, those of highest `\spadgloss{precedence}` are evaluated first. For arithmetic operators, `\spadop{**}` has highest precedence, `\spadop{*}` and `\spadop{/}` have the next highest precedence, and `\spadop{+}` and `\spadop{-}` have the lowest precedence.

```
\xctc{
Axiom puts implicit parentheses around operations of higher
precedence, and groups those of equal precedence from left to right.
}{
\spadpaste{1 + 2 - 3 / 4 * 3 ** 2 - 1}
}
\xctc{
The above expression is equivalent to this.
}{
\spadpaste{((1 + 2) - ((3 / 4) * (3 ** 2))) - 1}
}
\xctc{
If an expression contains subexpressions enclosed in parentheses,
the parenthesized subexpressions are evaluated first (from left to
right, from inside out).
}{
\spadpaste{1 + 2 - 3/ (4 * 3 ** (2 - 1))}

6.0.15 Some Types

⇒ “notitle” (ugTypesPage) 7.0.35 on page 1795

<ug01.ht>+≡

```
\begin{page}{ugIntroTypesPage}{1.3.3. Some Types}
\beginscroll
```

Everything in Axiom has a type.

The type determines what operations you can perform on an object and how the object can be used.

An entire chapter of this book (

`\downlink{‘‘Using Types and Modes’’}{ugTypesPage}`

in Chapter 2`\ignore{ugTypes}`) is dedicated to

the interactive use of types.

Several of the final chapters discuss how types are built and how they are organized in the Axiom library.

```
\xtc{
```

Positive integers are given type `\spadtype{PositiveInteger}`.

```
}{
```

```
\spadpaste{8}
```

```
}
```

```
\xtc{
```

Negative ones are given type `\spadtype{Integer}`.

This fine distinction is helpful to the

Axiom interpreter.

```
}{
```

```
\spadpaste{-8}
```

```
}
```

```
\xtc{
```

Here a positive integer exponent gives a polynomial result.

```
}{
```

```
\spadpaste{x**8}
```

```
}
```

```
\xtc{
```

Here a negative integer exponent produces a fraction.

```
}{
```

```
\spadpaste{x**(-8)}
```

```
}
```

```

6.0.16 Symbols, Variables, Assignments, and Declarations

⇒ “notitle” (ugLangAssignPage) 9.0.75 on page 1952

`<ug01.ht>+≡`

```
\begin{page}{ugIntroAssignPage}
{1.3.4. Symbols, Variables, Assignments, and Declarations}
\beginscroll
```

A `\spadgloss{symbol}` is a literal used for the input of things like the “variables” in polynomials and power series.

```
\labelSpace{2pc}
\xtc{
We use the three symbols \axiom{x}, \axiom{y}, and \axiom{z} in
entering this polynomial.
}{
\spadpaste{(x - y*z)**2}
}
```

A symbol has a name beginning with an uppercase or lowercase alphabetic character, `\axiomSyntax{\%}`, or `\axiomSyntax{!}`. Successive characters (if any) can be any of the above, digits, or `\axiomSyntax{?}`. Case is distinguished: the symbol `\axiom{points}` is different from the symbol `\axiom{Points}`.

A symbol can also be used in Axiom as a `\spadgloss{variable}`. A variable refers to a value. To `\spadglossSee{assign}{assignment}` a value to a variable, the operator `\axiomSyntax{:=}` is used. `\footnote{Axiom actually has two forms of assignment: {\it immediate} assignment, as discussed here, and {\it delayed assignment}. See \downlink{“Immediate and Delayed Assignments”} {ugLangAssignPage} in Section 5.1\ignore{ugLangAssign} for details.}` A variable initially has no restrictions on the kinds of values to which it can refer.

```
\xtc{
This assignment gives the value \axiom{4} (an integer) to
a variable named \axiom{x}.
}{
\spadpaste{x := 4}
}
\xtc{
This gives the value \axiom{z + 3/5} (a polynomial) to \axiom{x}.
}{
```

```

\spadpaste{x := z + 3/5}
}
\xtc{
To restrict the types of objects that can be assigned to a variable,
use a \spadgloss{declaration}
}{
\spadpaste{y : Integer \bound{y}}
}
\xtc{
After a variable is declared to be of some type, only values
of that type can be assigned to that variable.
}{
\spadpaste{y := 89\bound{y1}\free{y}}
}
\xtc{
The declaration for \axiom{y} forces values assigned to \axiom{y} to
be converted to integer values.
}{
\spadpaste{y := sin \%pi}
}
\xtc{
If no such conversion is possible,
Axiom refuses to assign a value to \axiom{y}.
}{
\spadpaste{y := 2/3}
}
\xtc{
A type declaration can also be given together with an assignment.
The declaration can assist Axiom in choosing the correct
operations to apply.
}{
\spadpaste{f : Float := 2/3}
}

```

Any number of expressions can be given on input line.
Just separate them by semicolons.
Only the result of evaluating the last expression is displayed.

```

\xtc{
These two expressions have the same effect as
the previous single expression.
}{
\spadpaste{f : Float; f := 2/3 \bound{fff}}
}

```

The type of a symbol is either \axiomType{Symbol}

or `\axiomType{Variable({\it name})}` where `{\it name}` is the name of the symbol.

```
\xctc{
By default, the interpreter
gives this symbol the type \axiomType{Variable(q)}.
}{
\spadpaste{q}
}
\xctc{
When multiple symbols are involved, \axiomType{Symbol} is used.
}{
\spadpaste{[q, r]}
}

\xctc{
What happens when you try to use a symbol that is the name of a variable?
}{
\spadpaste{f \free{fff}}
}
\xctc{
Use a single quote (\axiomSyntax{'}) before
the name to get the symbol.
}{
\spadpaste{'f}
}
```

Quoting a name creates a symbol by preventing evaluation of the name as a variable. Experience will teach you when you are most likely going to need to use a quote.

We try to point out the location of such trouble spots.

```

6.0.17 Conversion

⇒ “notitle” (ugTypesConvertPage) 7.0.50 on page 1864

<ug01.ht>+≡

```
\begin{page}{ugIntroConversionPage}{1.3.5. Conversion}
\beginscroll
```

Objects of one type can usually be “converted” to objects of several other types. To \spadglossSee{convert}{conversion} an object to a new type, use the \axiomSyntax{::} infix operator.\footnote{Conversion is discussed in detail in \downlink{‘‘Conversion’’}{ugTypesConvertPage} in Section 2.7\ignore{ugTypesConvert}.} For example, to display an object, it is necessary to convert the object to type \spadtype{OutputForm}.

```
\xtc{
This produces a polynomial with rational number coefficients.
}{
\spadpaste{p := r**2 + 2/3 \bound{p}}
}
\xtc{
Create a quotient of polynomials with integer coefficients
by using \axiomSyntax{::}.
}{
\spadpaste{p :: Fraction Polynomial Integer \free{p}}
}
```

Some conversions can be performed automatically when Axiom tries to evaluate your input.
Others conversions must be explicitly requested.

```

6.0.18 Calling Functions

<ug01.ht>+≡

```
\begin{page}{ugIntroCallFunPage}{1.3.6. Calling Functions}
\beginscroll
```

As we saw earlier, when you want to add or subtract two values, you place the arithmetic operator `\spadop{+}` or `\spadop{-}` between the two

`\spadglossSee{arguments}{argument}` denoting the values.

To use most other Axiom operations, however, you use another syntax: write the name

of the operation first, then an open parenthesis, then each of the arguments separated by commas, and, finally, a closing parenthesis.

If the operation takes only one argument and the argument is a number or a symbol, you can omit the parentheses.

```
\xctc{
```

This calls the operation `\axiomFun{factor}` with the single integer argument `\axiom{120}`.

```
}{
```

```
\spadpaste{factor(120)}
```

```
}
```

```
\xctc{
```

This is a call to `\axiomFun{divide}` with the two integer arguments `\axiom{125}` and `\axiom{7}`.

```
}{
```

```
\spadpaste{divide(125,7)}
```

```
}
```

```
\xctc{
```

This calls `\axiomFun{quatern}` with four floating-point arguments.

```
}{
```

```
\spadpaste{quatern(3.4,5.6,2.9,0.1)}
```

```
}
```

```
\xctc{
```

This is the same as `\axiom{factorial(10)}`.

```
}{
```

```
\spadpaste{factorial 10}
```

```
}
```

An operations that returns a `\spadtype{Boolean}` value (that is, `\spad{true}` or `\spad{false}`) frequently has a name suffixed with a question mark ('?'). For example, the `\spadfun{even?}`

operation returns `\spad{true}` if its integer argument is an even number, `\spad{false}` otherwise.

An operation that can be destructive on one or more arguments usually has a name ending in a exclamation point ('!'). This actually means that it is {\it allowed} to update its arguments but it is not {\it required} to do so. For example, the underlying representation of a collection type may not allow the very last element to be removed and so an empty object may be returned instead. Therefore, it is important that you use the object returned by the operation and not rely on a physical change having occurred within the object. Usually, destructive operations are provided for efficiency reasons.

\begin{page}{ugIntroGraphicsPage}{1.4. Graphics}
\beginscroll
%
```

Axiom has a two- and three-dimensional drawing and rendering package that allows you to draw, shade, color, rotate, translate, map, clip, scale and combine graphic output of Axiom computations. The graphics interface is capable of plotting functions of one or more variables and plotting parametric surfaces. Once the graphics figure appears in a window, move your mouse to the window and click. A control panel appears immediately and allows you to interactively transform the object.

```
\psXtc{
This is an example of Axiom's two-dimensional plotting. From the 2D
Control Panel you can rescale the plot, turn axes and units on and off
and save the image, among other things. This PostScript image was
produced by clicking on the
\texht{\fbox{\bf PS}}{\bf PS} 2D Control Panel button.
}{

  \begin{page}{ugIntroNumbersPage}{1.5. Numbers}
  \beginscroll
  %

```

Axiom distinguishes very carefully between different kinds of numbers, how they are represented and what their properties are.

Here are a sampling of some of these kinds of numbers and some things you can do with them.

```

\xtc{
Integer arithmetic is always exact.
}

```

```

\spadpaste{11**13 * 13**11 * 17**7 - 19**5 * 23**3}
}
\xtc{
Integers can be represented in factored form.
}{
\spadpaste{factor 643238070748569023720594412551704344145570763243
\bound{ex1}}
}
\xtc{
Results stay factored when you do arithmetic.
Note that the \axiom{12} is automatically factored for you.
}{
\spadpaste{\% * 12 \free{ex1}}
}
\xtc{
Integers can also be displayed to bases other than 10.
This is an integer in base 11.
}{
\spadpaste{radix(25937424601,11)}
}
\xtc{
Roman numerals are also available for those special occasions.
}{
\spadpaste{roman(1992)}
}
\xtc{
Rational number arithmetic is also exact.
}{
\spadpaste{r := 10 + 9/2 + 8/3 + 7/4 + 6/5 + 5/6 + 4/7 + 3/8 + 2/9
\bound{r}}
}
\xtc{
To factor fractions, you have to
map \axiomFun{factor} onto the numerator and denominator.
}{
\spadpaste{map(factor,r) \free{r}}
}
\xtc{
Type \spadtype{SingleInteger} refers to machine word-length
integers.
In English, this expression means ‘‘\axiom{11} as a small
integer’’.
}{
\spadpaste{11@SingleInteger}
}
\xtc{

```

Machine double-precision floating-point numbers are also available for numeric and graphical applications.

```
{
\spadpaste{123.21@DoubleFloat}
}
```

The normal floating-point type in Axiom, `\spadtype{Float}`, is a software implementation of floating-point numbers in which the exponent and the mantissa may have any number of digits.^{\footnote{See}
`\downlink{‘Float’}{FloatXmpPage}\ignore{Float}` and
`\downlink{‘DoubleFloat’}{DoubleFloatXmpPage}\ignore{DoubleFloat}` for additional information on floating-point types.
The types `\spadtype{Complex(Float)}` and
`\spadtype{Complex(DoubleFloat)}` are the corresponding software implementations of complex floating-point numbers.

```
\xctc{
This is a floating-point approximation to about twenty digits.
The \axiomSyntax{::}
is used here to change from one kind of object
(here, a rational number) to another (a floating-point number).
}{
\spadpaste{r :: Float \free{r}}
}
\xctc{
Use \spadfunFrom{digits}{Float} to change the number of digits in
the representation.
This operation returns the previous value so you can reset it
later.
}{
\spadpaste{digits(22) \bound{fewerdigits}}
}
\xctc{
To \axiom{22} digits of precision, the number
\texht{$e^{\pi \sqrt{163.0}}}$\axiom{exp(\%pi * sqrt 163.0)}
appears to be an integer.
}{
\spadpaste{exp(\%pi * sqrt 163.0) \free{fewerdigits}}
}
\xctc{
Increase the precision to forty digits and try again.
}{
\spadpaste{digits(40); exp(\%pi * sqrt 163.0) \free{moredigits}}
}
```

```

\xtc{
Here are complex numbers with rational numbers as real and
imaginary parts.
}{
\spadpaste{(2/3 + \%i)**3 \bound{gaussint}}
}
\xtc{
The standard operations on complex numbers are available.
}{
\spadpaste{conjugate \% \free{gaussint}}
}
\xtc{
You can factor complex integers.
}{
\spadpaste{factor(89 - 23 * \%i)}
}
\xtc{
Complex numbers with floating point parts are also available.
}{
\spadpaste{exp(\%pi/4.0 * \%i)}
}
\xtc{
Every rational number has an exact representation as a
repeating decimal expansion
(see \downlink{'DecimalExpansion'}{DecimalExpansionXmpPage}
\ignore{DecimalExpansion}).
}{
\spadpaste{decimal(1/352)}
}
\xtc{
A rational number can also be expressed as a continued fraction (see
\downlink{'ContinuedFraction'}{ContinuedFractionXmpPage}
\ignore{ContinuedFraction}).
}{
\spadpaste{continuedFraction(6543/210)}
}
\xtc{
Also, partial fractions can be used and can be displayed in a
compact \ldots
}{
\spadpaste{partialFraction(1,factorial(10)) \bound{partfrac}}
}
\xtc{
or expanded format (see
\downlink{'PartialFraction'}{PartialFractionXmpPage}
\ignore{PartialFraction}).
}

```

```

}{
\spadpaste{padicFraction(\%) \free{partfrac}}
}
\xtc{
Like integers, bases (radices) other than ten can be used for rational
numbers (see
\downlink{'RadixExpansion'}{RadixExpansionXmpPage}
\ignore{RadixExpansion}).
Here we use base eight.
}{
\spadpaste{radix(4/7, 8)\bound{rad}}
}
\xtc{
Of course, there are complex versions of these as well.
Axiom decides to make the result a complex rational number.
}{
\spadpaste{\% + 2/3*\%i\free{rad}}
}
\xtc{
You can also use Axiom to manipulate fractional powers.
}{
\spadpaste{(5 + sqrt 63 + sqrt 847)**(1/3)}
}
\xtc{
You can also compute with integers modulo a prime.
}{
\spadpaste{x : PrimeField 7 := 5 \bound{x}}
}
\xtc{
Arithmetic is then done modulo \math0rSpad{7}.
}{
\spadpaste{x**3 \free{x}}
}
\xtc{
Since \math0rSpad{7} is prime, you can invert nonzero values.
}{
\spadpaste{1/x \free{x}}
}
\xtc{
You can also compute modulo an integer that is not a prime.
}{
\spadpaste{y : IntegerMod 6 := 5 \bound{y}}
}
\xtc{
All of the usual arithmetic operations are available.
}{

```

```

\spadpaste{y**3 \free{y}}
}
\xtc{
Inversion is not available if the modulus is not a prime
number.
Modular arithmetic and prime fields are discussed in
\downlink{'Modular Arithmetic and Prime Fields'}
{ugxProblemFinitePrimePage}
in Section 8.11.1\ignore{ugxProblemFinitePrime}.
}{
\spadpaste{1/y \free{y}}
}
\xtc{
This defines \axiom{a} to be an algebraic number, that is,
a root of a polynomial equation.
}{
\spadpaste{a := rootOf(a**5 + a**3 + a**2 + 3,a) \bound{a}}
}
\xtc{
Computations with \axiom{a} are reduced according
to the polynomial equation.
}{
\spadpaste{(a + 1)**10\free{a}}
}
\xtc{
Define \axiom{b} to be an algebraic number involving \axiom{a}.
}{
\spadpaste{b := rootOf(b**4 + a,b) \bound{b}\free{a}}
}
\xtc{
Do some arithmetic.
}{
\spadpaste{2/(b - 1) \free{b}\bound{check}}
}
\xtc{
To expand and simplify this, call \axiomFun{ratDenom}
to rationalize the denominator.
}{
\spadpaste{ratDenom(\%) \free{check}\bound{check1}}
}
\xtc{
If we do this, we should get \axiom{b}.
}{
\spadpaste{2/\%+1 \free{check1}\bound{check2}}
}
\xtc{

```

But we need to rationalize the denominator again.

```
{
\spadpaste{ratDenom(\%) \free{check2}}
}
\xtc{
Types \spadtype{Quaternion} and \spadtype{Octonion} are also available.
Multiplication of quaternions is non-commutative, as expected.
}{
\spadpaste{q:=quatern(1,2,3,4)*quatern(5,6,7,8) -
quatern(5,6,7,8)*quatern(1,2,3,4)}

```
\begin{page}{ugIntroCollectPage}{1.6. Data Structures}
\beginscroll
%
```

Axiom has a large variety of data structures available. Many data structures are particularly useful for interactive computation and others are useful for building applications. The data structures of Axiom are organized into `\spadglossSee{category hierarchies}{hierarchy}` as shown on the inside back cover.

A `\spadgloss{list}` is the most commonly used data structure in Axiom for holding objects all of the same type. `\footnote{Lists are discussed in`
`\downlink{‘List’}{ListXmpPage}\ignore{List}` and in
`\downlink{‘‘Creating Lists and Streams with Iterators’’}`
`{ugLangItsPage}` in Section 5.5 `\ignore{ugLangIts}.`
 The name `{\it list}` is short for ‘‘linked-list of nodes.’’ Each node consists of a value (`\spadfunFrom{first}{List}`) and a link (`\spadfunFrom{rest}{List}`) that
`\spadglossSee{points}{pointer}` to the next node, or to a

distinguished value denoting the empty list.
 To get to, say, the third element, Axiom starts at the front
 of the list, then traverses across two links to the third node.

```
\xrc{
Write a list of elements using
square brackets with commas separating the elements.
}{
\spadpaste{u := [1,-7,11] \bound{u}}
}
\xrc{
This is the value at the third node.
Alternatively, you can say \axiom{u.3}.
}{
\spadpaste{first rest rest u\free{u}}
}
```

Many operations are defined on lists, such as:
`\axiomFun{empty?}`, to test that a list has no elements;
`\axiomFun{cons}\axiom{(x,l)}`, to create a new list with
`\axiomFun{first}` element `\axiom{x}` and `\axiomFun{rest} \axiom{l}`;
`\axiomFun{reverse}`, to create a new list with elements in reverse
 order; and `\axiomFun{sort}`, to arrange elements in order.

An important point about lists is that they are ‘mutable’: their
 constituent elements and links can be changed ‘in place.’
 To do this, use any of the operations whose names end with the
 character `\axiomSyntax{!}`.

```
\xrc{
The operation \spadfunFromX{concat}{List}\axiom{(u,v)}
replaces the last link of the list
\axiom{u} to point to some other list \axiom{v}.
Since \axiom{u} refers to the original list,
this change is seen by \axiom{u}.
}{
\spadpaste{concat!(u,[9,1,3,-4]); u\free{u}\bound{u1}}
}
\xrc{
A {\it cyclic list} is a list with a ‘cycle’:
a link pointing back to an earlier node of the list.
To create a cycle, first get a node somewhere down
the list.
}{
\spadpaste{lastnode := rest(u,3)\free{u1}\bound{u2}}
}
```

```

\xtc{
Use \spadfunFromX{setrest}{List} to
change the link emanating from that node to point back to an
earlier part of the list.
}{
\spadpaste{setrest!(lastnode,rest(u,2)); u\free{u2}}
}

```

A `\spadgloss{stream}` is a structure that (potentially) has an infinite number of distinct elements. `\footnote{Streams are discussed in \downlink{‘Stream’}{StreamXmpPage}\ignore{Stream} and in \downlink{‘Creating Lists and Streams with Iterators’}{ugLangItsPage} in Section 5.5\ignore{ugLangIts}.}` Think of a stream as an “infinite list” where elements are computed successively.

```

\xtc{
Create an infinite stream of factored integers.
Only a certain number of initial elements are computed
and displayed.
}{
\spadpaste{[factor(i) for i in 2.. by 2] \bound{stream1}}
}
\xtc{
Axiom represents streams by a collection of already-computed
elements together with a function to compute the next element
“on demand.”
Asking for the \eth{\axiom{n}} element causes elements \axiom{1} through
\axiom{n} to be evaluated.
}{
\spadpaste{\%.36 \free{stream1}}
}

```

Streams can also be finite or cyclic. They are implemented by a linked list structure similar to lists and have many of the same operations. For example, `\axiomFun{first}` and `\axiomFun{rest}` are used to access elements and successive nodes of a stream.

```

%%> reverse and sort do not exist for streams
%%Don't try to reverse or sort a stream: the
%%operation will generally run forever!

```

A `\spadgloss{one-dimensional array}` is another data structure used to hold objects of the same type. `\footnote{See \downlink{‘OneDimensionalArray’}{OneDimensionalArrayXmpPage}}`

\ignore{OneDimensionalArray} for details.}

Unlike lists, one-dimensional arrays are inflexible---they are implemented using a fixed block of storage. Their advantage is that they give quick and equal access time to any element.

```
\xctc{
A simple way to create a one-dimensional array is to apply the
operation \axiomFun{oneDimensionalArray} to a list of elements.
}{
\spadpaste{a := oneDimensionalArray [1, -7, 3, 3/2]\bound{a}}
}
\xctc{
One-dimensional arrays are also mutable:
you can change their constituent elements ‘‘in place.’’
}{
\spadpaste{a.3 := 11; a\bound{a1}\free{a}}
}
\xctc{
However, one-dimensional arrays are not flexible structures.
You cannot destructively \spadfunX{concat} them together.
}{
\spadpaste{concat!(a,oneDimensionalArray [1,-2])\free{a1}}
}
```

Examples of datatypes similar to \spadtype{OneDimensionalArray} are: \spadtype{Vector} (vectors are mathematical structures implemented by one-dimensional arrays), \spadtype{String} (arrays of ‘‘characters,’’ represented by byte vectors), and \spadtype{Bits} (represented by ‘‘bit vectors’’).

```
\xctc{
A vector of 32 bits,
each representing the \spadtype{Boolean} value \axiom{true}.
}{
\spadpaste{bits(32,true)}
}
```

A \spadgloss{flexible array} is a cross between a list and a one-dimensional array.\footnote{See \downlink{‘FlexibleArray’}{FlexibleArrayXmpPage}\ignore{FlexibleArray} for details.}

Like a one-dimensional array, a flexible array occupies a fixed block of storage.

Its block of storage, however, has room to expand!

When it gets full, it grows (a new, larger block of storage is allocated); when it has too much room, it contracts.

```
\xhc{
Create a flexible array of three elements.
}{
\spadpaste{f := flexibleArray [2, 7, -5]\bound{f}}
}
\xhc{
Insert some elements between the second and third elements.
}{
\spadpaste{insert!(flexibleArray [11, -3],f,2)\free{f}}
}
```

Flexible arrays are used to implement ‘‘heaps.’’ A `\spadgloss{heap}` is an example of a data structure called a `\spadgloss{priority queue}`, where elements are ordered with respect to one another.^{\footnote{See \downlink{‘Heap’}{HeapXmpPage}\ignore{Heap} for more details.}} Heaps are also examples of data structures called `\spadglossSee{bags}{bag}`. Other bag data structures are `\spadtype{Stack}`, `\spadtype{Queue}`, and `\spadtype{Dequeue}`. A heap is organized so as to optimize insertion and extraction of maximum elements. The `\spadfunX{extract}` operation returns the maximum element of the heap, after destructively removing that element and reorganizing the heap so that the next maximum element is ready to be delivered.

```
\xhc{
An easy way to create a heap is to apply the
operation \spadfun{heap} to a list of values.
}{
\spadpaste{h := heap [-4,7,11,3,4,-7]\bound{h}}
}
\xhc{
This loop extracts elements one-at-a-time from \spad{h}
until the heap is exhausted, returning the elements
as a list in the order they were extracted.
}{
\spadpaste{[extract!(h) while not empty?(h)]\free{h}}
}
```

A `\spadgloss{binary tree}` is a ‘‘tree’’ with at most two branches per

node: it is either empty, or else is a node consisting of a value, and a left and right subtree (again, binary trees).\footnote{Example of binary tree types are \spadtype{BinarySearchTree} (see \downlink{‘BinarySearchTree’}{BinarySearchTreeXmpPage} \ignore{BinarySearchTree}, \spadtype{PendantTree}, \spadtype{TournamentTree}, and \spadtype{BalancedBinaryTree} (see \downlink{‘BalancedBinaryTree’}{BalancedBinaryTreeXmpPage} \ignore{BalancedBinaryTree}).}

```
\xctc{
A {\it binary search tree} is a binary tree such that,
for each node, the value of the node is
greater than all values (if any) in the left subtree,
and less than or equal all values (if any) in the right subtree.
}{
\spadpaste{binarySearchTree [5,3,2,9,4,7,11]}
}
```

```
\xctc{
A {\it balanced binary tree} is useful for doing modular computations.
Given a list \axiom{lm} of moduli,
\axiomFun{modTree}\axiom{(a,lm)} produces a balanced binary
tree with the values \texht{$a \bmod m$}{a {\tt mod} m}
at its leaves.
}{
\spadpaste{modTree(8,[2,3,5,7])}
}
```

A \spadgloss{set} is a collection of elements where duplication and order is irrelevant.\footnote{See \downlink{‘Set’}{SetXmpPage}\ignore{Set} for more details.}

Sets are always finite and have no corresponding structure like streams for infinite collections.

```
\xctc{
%Create sets using braces (\axiomSyntax{\{ } and \axiomSyntax{\}})
%rather than brackets.
}{
\spadpaste{fs := set [1/3,4/5,-1/3,4/5] \bound{fs}}
}
```

A \spadgloss{multiset} is a set that keeps track of the number of duplicate values.\footnote{See \downlink{‘MultiSet’}{MultiSetXmpPage}\ignore{MultiSet} for details.}

```

\xtc{
For all the primes \axiom{p} between 2 and 1000, find the
distribution of \texht{$p \bmod 5$}{ $p \bmod 5$ }.
}{
\spadpaste{multiset [x rem 5 for x in primes(2,1000)]}
}

A \spadgloss{table}
is conceptually a set of ‘‘key--value’’ pairs and
is a generalization of a multiset.\footnote{For examples of tables, see
\spadtype{AssociationList} (
\downlink{‘AssociationList’}{AssociationListXmpPage}
\ignore{AssociationList}),
\spadtype{HashTable},
\spadtype{KeyedAccessFile} (
\downlink{‘KeyedAccessFile’}{KeyedAccessFileXmpPage}
\ignore{KeyedAccessFile}),
\spadtype{Library} (\downlink{‘Library’}{LibraryXmpPage}
\ignore{Library}),
\spadtype{SparseTable} (
\downlink{‘SparseTable’}{SparseTableXmpPage}\ignore{SparseTable}),
\spadtype{StringTable} (
\downlink{‘StringTable’}{StringTableXmpPage}\ignore{StringTable}),
and \spadtype{Table} (\downlink{‘Table’}{TableXmpPage}\ignore{Table}).}
The domain \spadtype{Table(Key, Entry)} provides a general-purpose
type for tables with {\it values} of type \axiom{Entry} indexed
by {\it keys} of type \axiom{Key}.

```

```

\xtc{
Compute the above distribution of primes using tables.
First, let \axiom{t} denote an empty table of keys and values,
each of type \spadtype{Integer}.
}{
\spadpaste{t : Table(Integer,Integer) := empty()\bound{t}}
}

```

We define a function \userfun{howMany} to return the number of values of a given modulus \axiom{k} seen so far. It calls \axiomFun{search}\axiom{(k,t)} which returns the number of values stored under the key \axiom{k} in table \axiom{t}, or \axiom{"failed"} if no such value is yet stored in \axiom{t} under \axiom{k}.

```

\xtc{
In English, this says ‘‘Define \axiom{howMany(k)} as follows.
First, let \smath{n} be the value of \axiomFun{search}\smath{(k,t)}.
```

```

Then, if \smath{n} has the value \smath{"failed"}, return the value
\smath{1}; otherwise return \smath{n + 1}.'''
}{
\spadpaste{howMany(k) == (n:=search(k,t); n case "failed" => 1; n+1)
\bound{how}}
}
\xtc{
Run through the primes to create the table, then print the table.
The expression \axiom{t.m := howMany(m)} updates the value in table \axiom{t}
stored under key \axiom{m}.
}{
\spadpaste{for p in primes(2,1000) repeat (m:= p rem 5; t.m:= howMany(m));
t\free{how t}}
}

```

A {\it record}
 is an example of an inhomogeneous collection
 of objects.\footnote{See
[\downlink{'Records'}\{ugTypesRecordsPage}](#)
 in Section 2.4\ignore{ugTypesRecords} for details.}
 A record consists of a set of named {\it selectors} that
 can be used to access its components.

```

\xtc{
Declare that \axiom{daniel} can only be
assigned a record with two prescribed fields.
}{
\spadpaste{daniel : Record(age : Integer, salary : Float) \bound{danieldec}}
}
\xtc{
Give \axiom{daniel} a value, using square brackets to enclose the values of
the fields.
}{
\spadpaste{daniel := [28, 32005.12] \free{danieldec}\bound{daniel}}
}
\xtc{
Give \axiom{daniel} a raise.
}{
\spadpaste{daniel.salary := 35000; daniel \free{daniel}}
}

```

A {\it union}
 is a data structure used when objects
 have multiple types.\footnote{See
[\downlink{'Unions'}\{ugTypesUnionsPage}](#)
 in Section 2.5\ignore{ugTypesUnions} for details.}

```

\xtc{
Let \axiom{dog} be either an integer or a string value.
}{
\spadpaste{dog: Union(licenseNumber: Integer, name: String)\bound{xint}}
}
\xtc{
Give \axiom{dog} a name.
}{
\spadpaste{dog := "Whisper"\free{xint}}
}

```

All told, there are over forty different data structures in Axiom.

Using the domain constructors described in

\downlink{'Domains'}{ugDomainsPage}

in Chapter 13\ignore{ugDomains}, you

can add your own data structure or extend an existing one.

Choosing the right data structure for your application may be the key to obtaining good performance.

To get higher dimensional aggregates, you can create one-dimensional aggregates with elements that are themselves aggregates, for example, lists of lists, one-dimensional arrays of lists of multisets, and so on. For applications requiring two-dimensional homogeneous aggregates, you will likely find `\it two-dimensional arrays` and `\it matrices` most useful.

The entries in `\spadtype{TwoDimensionalArray}` and `\spadtype{Matrix}` objects are all the same type, except that those for `\spadtype{Matrix}` must belong to a `\spadtype{Ring}`. You create and access elements in roughly the same way. Since matrices have an understood algebraic structure, certain algebraic operations are available for matrices but not for arrays. Because of this, we limit our discussion here to `\spadtype{Matrix}`, that can be regarded as an extension of `\spadtype{TwoDimensionalArray}`.^{\footnote{See \downlink{‘TwoDimensionalArray’}{TwoDimensionalArrayXmpPage} \ignore{TwoDimensionalArray} for more information about arrays.}} For more information about Axiom’s linear algebra facilities, see `\downlink{‘Matrix’}{MatrixXmpPage} \ignore{Matrix}`, `\downlink{‘Permanent’}{PermanentXmpPage} \ignore{Permanent}`, `\downlink{‘SquareMatrix’}{SqMatrixXmpPage} \ignore{SquareMatrix}`, `\downlink{‘Vector’}{VectorXmpPage} \ignore{Vector}`, `\downlink{‘‘Computation of Eigenvalues and Eigenvectors’’}{ugProblemEigenPage}` in Section 8.4`\ignore{ugProblemEigen}` `\texht{(computation of eigenvalues and eigenvectors)}`, and `\downlink{‘‘Solution of Linear and Polynomial Equations’’}`

6.0.26 Writing Your Own Functions

⇒ “notitle” (ugUserPage) 10.0.95 on page 2043
 ⇒ “notitle” (ugInOutPage) 9.0.67 on page 1925

```
<ug01.ht>+≡
\begin{page}{ugIntroYouPage}{1.8. Writing Your Own Functions}
\beginscroll
%
```

Axiom provides you with a very large library of predefined operations and objects to compute with. You can use the Axiom library of constructors to create new objects dynamically of quite arbitrary complexity. For example, you can make lists of matrices of fractions of polynomials with complex floating point numbers as coefficients. Moreover, the library provides a wealth of operations that allow you to create and manipulate these objects.

For many applications, you need to interact with the interpreter and write some Axiom programs to tackle your application. Axiom allows you to write functions interactively, thereby effectively extending the system library. Here we give a few simple examples, leaving the details to `\downlink{‘‘User-Defined Functions, Macros and Rules’’}` `{ugUserPage}` in Chapter 6`\ignore{ugUser}`.

We begin by looking at several ways that you can define the “factorial” function in Axiom. The first way is to give a piece-wise definition of the function. This method is best for a general recurrence relation since the pieces are gathered together and compiled into an efficient iterative function. Furthermore, enough previously computed values are automatically saved so that a subsequent call to the function can pick up from where it left off.

```
\xtc{
Define the value of \userfun{fact} at \axiom{0}.
}{
\spadpaste{fact(0) == 1 \bound{fact}}
}
\xtc{
Define the value of \axiom{fact(n)} for general \axiom{n}.
}{
\spadpaste{fact(n) == n*fact(n-1)\bound{facta}\free{fact}}
}
\xtc{
Ask for the value at \axiom{50}.
```

The resulting function created by Axiom computes the value by iteration.

```

}{
\spadpaste{fact(50) \free{facta}}
}
\xtc{
A second definition uses an \axiom{if-then-else} and recursion.
}{
\spadpaste{fac(n) == if n < 3 then n else n * fac(n - 1) \bound{fac}}
}
\xtc{
This function is less efficient than the previous version since
each iteration involves a recursive function call.
}{
\spadpaste{fac(50) \free{fac}}
}
\xtc{
A third version directly uses iteration.
}{
\spadpaste{fa(n) == (a := 1; for i in 2..n repeat a := a*i; a) \bound{fa}}
}
\xtc{
This is the least space-consumptive version.
}{
\spadpaste{fa(50) \free{fa}}
}
\xtc{
A final version appears to construct a large list and then reduces over
it with multiplication.
}{
\spadpaste{f(n) == reduce(*,[i for i in 2..n]) \bound{f}}
}
\xtc{
In fact, the resulting computation is optimized into an efficient
iteration loop equivalent to that of the third version.
}{
\spadpaste{f(50) \free{f}}
}
\xtc{
The library version uses an algorithm that is different from the four
above because it highly optimizes the recurrence relation definition of
\axiomFun{factorial}.
}{
\spadpaste{factorial(50)}
}

```

You are not limited to one-line functions in Axiom.
 If you place your function definitions in {\bf .input} files
 (see \downlink{'Input Files'}{ugInOutInPage}
 in Section 4.1\ignore{ugInOutIn}), you can have
 multi-line functions that use indentation for grouping.

Given \axiom{n} elements, \axiomFun{diagonalMatrix} creates an
 \axiom{n} by \axiom{n} matrix with those elements down the diagonal.
 This function uses a permutation matrix
 that interchanges the \axiom{i}th and \axiom{j}th rows of a matrix
 by which it is right-multiplied.

```
\xctc{
This function definition shows a style of definition that can be used
in {\bf .input} files.
Indentation is used to create \spadglossSee{blocks}{block}\texht{\//}{:
sequences of expressions that are evaluated in sequence except as
modified by control statements such as \axiom{if-then-else} and \axiom{return}.
}{
\begin{spadsrc}[\bound{permMat}]
permMat(n, i, j) ==
  m := diagonalMatrix
    [(if i = k or j = k then 0 else 1)
     for k in 1..n]
  m(i,j) := 1
  m(j,i) := 1
  m
\end{spadsrc}
}
\xctc{
This creates a four by four matrix that interchanges the second and third
rows.
}{
\spadpaste{p := permMat(4,2,3) \free{permMat}\bound{p}}
}
\xctc{
Create an example matrix to permute.
}{
\spadpaste{m := matrix [[4*i + j for j in 1..4] for i in 0..3]\bound{m}}
}
\xctc{
Interchange the second and third rows of m.
}{
\spadpaste{permMat(4,2,3) * m \free{p m}}
}
```

A function can also be passed as an argument to another function, which then applies the function or passes it off to some other function that does.

You often have to declare the type of a function that has functional arguments.

```
\xctc{
This declares \userfun{t} to be a two-argument function that
returns a \spadtype{Float}.
The first argument is a function that takes one \spadtype{Float}
argument and returns a \spadtype{Float}.
}{
\spadpaste{t : (Float -> Float, Float) -> Float \bound{tdecl}}
}
\xctc{
This is the definition of \userfun{t}.
}{
\spadpaste{t(fun, x) == fun(x)**2 + sin(x)**2 \free{tdecl}\bound{t}}
}
\xctc{
We have not defined a \axiomFun{cos} in the workspace. The one from the
Axiom library will do.
}{
\spadpaste{t(cos, 5.2058) \free{t}}
}
\xctc{
Here we define our own (user-defined) function.
}{
\spadpaste{cosinv(y) == cos(1/y) \bound{cosinv}}
}
\xctc{
Pass this function as an argument to \userfun{t}.
}{
\spadpaste{t(cosinv, 5.2058) \free{t}\free{cosinv}}
}
```

Axiom also has pattern matching capabilities for simplification

of expressions and for defining new functions by rules.

For example, suppose that you want to apply regularly a transformation that groups together products of radicals:

$\sqrt{a} \sqrt{b} \mapsto \sqrt{ab}$, $\forall a, b$

$\sqrt{a} \sqrt{b} \mapsto \sqrt{a \cdot b}$ for any a and b

Note that such a transformation is not generally correct.

Axiom never uses it automatically.

```

\xtc{
Give this rule the name \userfun{groupSqrt}.
}{
\spadpaste{groupSqrt := rule(sqrt(a) * sqrt(b) == sqrt(a*b)) \bound{g}}
}
\xtc{
Here is a test expression.
}{
\spadpaste{a := (sqrt(x) + sqrt(y) + sqrt(z))*4 \bound{sxy}}
}
\xtc{
The rule
\userfun{groupSqrt} successfully simplifies the expression.
}{
\spadpaste{groupSqrt a \free{sxy} \free{g}}
}

6.0.27 Polynomials

```

<ug01.ht>+≡
\begin{page}{ugIntroVariablesPage}{1.9. Polynomials}
\beginscroll
%
```

Polynomials are the commonly used algebraic types in symbolic computation.

Interactive users of Axiom generally only see one type of polynomial: `\spadtype{Polynomial(R)}`.

This type represents polynomials in any number of unspecified variables over a particular coefficient domain `\axiom{R}`.

This type represents its coefficients

`\spadglossSee{sparse}`: only terms with non-zero coefficients are represented.

In building applications, many other kinds of polynomial representations are useful.

Polynomials may have one variable or multiple variables, the variables can be named or unnamed, the coefficients can be stored sparsely or densely.

So-called “distributed multivariate polynomials” store polynomials as coefficients paired with vectors of exponents.

This type is particularly efficient for use in algorithms for solving systems of non-linear polynomial equations.

```

\xtc{
The polynomial constructor most familiar to the interactive user
is \spadtype{Polynomial}.
}{
\spadpaste{(x**2 - x*y**3 + 3*y)**2}
}
\xtc{
If you wish to restrict the variables used,
\spadtype{UnivariatePolynomial}
provides polynomials in one variable.
}{
\spadpaste{p: UP(x,INT) := (3*x-1)**2 * (2*x + 8)}
}
\xtc{
The constructor
\spadtype{MultivariatePolynomial} provides polynomials in one or more
specified variables.
}{
\spadpaste{m: MPOLY([x,y],INT) := (x**2-x*y**3+3*y)**2 \bound{m}}
```

```

}
\xtc{
You can change the way the polynomial appears by modifying the variable
ordering in the explicit list.
}{
\spadpaste{m :: MPOLY([y,x],INT) \free{m}}
}
\xtc{
The constructor
\spadtype{DistributedMultivariatePoly} provides
polynomials in one or more specified variables with the monomials
ordered lexicographically.
}{
\spadpaste{m :: DMP([y,x],INT) \free{m}}
}
\xtc{
The constructor
\spadtype{HomogeneousDistributedMultivariatePoly} is similar
except that the monomials are ordered by total order refined by
reverse lexicographic order.
}{
\spadpaste{m :: HDMP([y,x],INT) \free{m}}
}

```

More generally, the domain constructor
`\spadtype{GeneralDistributedMultivariatePoly}` allows the
user to provide an arbitrary predicate to define his own term ordering.
These last three constructors are typically used in
`\texht{Gr\{"o}bner}{Groebner}` basis
applications and when a flat (that is, non-recursive) display is
wanted and the term ordering is critical for controlling the computation.

6.0.28 Limits

⇒ “notitle” (ugProblemLimitsPage) 12.0.161 on page 2414

`<ug01.ht>+≡`

```
\begin{page}{ugIntroCalcLimitsPage}{1.10. Limits}
\beginscroll
%
```

Axiom’s `\axiomFun{limit}` function is usually used to evaluate limits of quotients where the numerator and denominator both tend to zero or both tend to infinity. To find the limit of an expression `\axiom{f}` as a real variable `\axiom{x}` tends to a limit value `\axiom{a}`, enter `\axiom{limit(f, x=a)}`. Use `\axiomFun{complexLimit}` if the variable is complex. Additional information and examples of limits are in `\downlink{‘Limits’}{ugProblemLimitsPage}` in Section 8.6\ignore{ugProblemLimits}.

```
\xctc{
You can take limits of functions with parameters.
}{
\spadpaste{g := csc(a*x) / csch(b*x) \bound{g}}
}
\xctc{
As you can see, the limit is expressed in terms of the parameters.
}{
\spadpaste{limit(g,x=0) \free{g}}
}
%
\xctc{
A variable may also approach plus or minus infinity:
}{
\spadpaste{h := (1 + k/x)**x \bound{h}}
}
\xctc{
\texht{Use \axiom{\%plusInfinity} and \axiom{\%minusInfinity} to
denote $\infty$ and $-\infty$.}{
}{
\spadpaste{limit(h,x=\%plusInfinity) \free{h}}
}
}
\xctc{
A function can be defined on both sides of a particular value, but may
tend to different limits as its variable approaches that value from
the left and from the right.
```

```

}{
\spadpaste{limit(sqrt(y**2)/y,y = 0)}
}
\xtc{
As \axiom{x} approaches \axiom{0} along the real axis, \axiom{exp(-1/x**2)}
tends to \axiom{0}.
}{
\spadpaste{limit(exp(-1/x**2),x = 0)}
}
\xtc{
However, if \axiom{x} is allowed to approach \axiom{0} along any path
in the complex plane, the limiting value of \axiom{exp(-1/x**2)}
depends on the path taken because the function has an essential
singularity at \axiom{x=0}. This is reflected in the error message
returned by the function.
}{
\spadpaste{complexLimit(exp(-1/x**2),x = 0)}
}

6.0.29 Series

⇒ “notitle” (ugProblemSeriesPage) 12.0.164 on page 2436

`<ug01.ht>+≡`

```
\begin{page}{ugIntroSeriesPage}{1.11. Series}
\beginscroll
%
```

Axiom also provides power series.

By default, Axiom tries to compute and display the first ten elements of a series.

Use `\spadsys{set streams calculate}` to change the default value to something else.

For the purposes of this book, we have used this system command to display fewer than ten terms.

For more information about working with series, see

`\downlink{‘‘Working with Power Series’’}{ugProblemSeriesPage}` in Section 8.9\ignore{ugProblemSeries}.

```
\xtc{
```

You can convert a functional expression to a power series by using the operation `\axiomFun{series}`.

In this example,

`\axiom{sin(a*x)}` is expanded in powers of `\axiom{(x - 0)}`, that is, in powers of `\axiom{x}`.

```
}{
\spadpaste{series(sin(a*x),x = 0)}
}
```

```
\xtc{
```

This expression expands

`\axiom{sin(a*x)}` in powers of `\axiom{(x - %pi/4)}`.

```
}{
\spadpaste{series(sin(a*x),x = %pi/4)}
}
```

```
\xtc{
```

Axiom provides

`{\it Puiseux series:}`

series with rational number exponents.

The first argument to `\axiomFun{series}` is an in-place function that computes the `\eth{\axiom{n}}` coefficient.

(Recall that

the `\axiomSyntax{+-->}` is an infix operator meaning ‘‘maps to.’’)

```
}{
```

```
\spadpaste{
```

```

series(n --> (-1)**((3*n - 4)/6)/factorial(n - 1/3), x = 0, 4/3.., 2)}
}
\xtc{
Once you have created a power series, you can perform arithmetic operations
on that series.
We compute the Taylor expansion of \axiom{1/(1-x)}.
}{
\spadpaste{f := series(1/(1-x), x = 0) \bound{f}}
}
\xtc{
Compute the square of the series.
}{
\spadpaste{f ** 2 \free{f}}
}
\xtc{
The usual elementary functions
(\axiomFun{log}, \axiomFun{exp}, trigonometric functions, and so on)
are defined for power series.
}{
\spadpaste{f := series(1/(1-x), x = 0) \bound{f1}}
}
\xtc{
}{
\spadpaste{g := log(f) \free{f1}\bound{g}}
}
\xtc{
}{
\spadpaste{exp(g) \free{g}}
}
\xtc{
Here is a way to obtain numerical approximations of
\axiom{e} from the Taylor series expansion of \axiom{exp(x)}.
First create the desired Taylor expansion.
}{
\spadpaste{f := taylor(exp(x)) \bound{f2}}
}
\xtc{
Evaluate the series at the value \axiom{1.0}.
As you see, you get a sequence of partial sums.
}{
\spadpaste{eval(f, 1.0) \free{f2}}
}

6.0.30 Derivatives

```

<ug01.ht>+≡
\begin{page}{ugIntroCalcDerivPage}{1.12. Derivatives}
\beginscroll
%
Use the Axiom function \axiomFun{D} to differentiate an
expression.

\texht{\vskip 2pc}{ }
\xtc{
To find the derivative of an expression \axiom{f} with respect to a
variable \axiom{x}, enter \axiom{D(f, x)}.
}{
\spadpaste{f := exp exp x \bound{f}}
}
\xtc{
}{
\spadpaste{D(f, x) \free{f}}
}
\xtc{
An optional third argument \axiom{n} in \axiomFun{D} asks
Axiom for the \eth{\axiom{n}} derivative of \axiom{f}.
This finds the fourth derivative of \axiom{f} with respect to \axiom{x}.
}{
\spadpaste{D(f, x, 4) \free{f}}
}
\xtc{
You can also compute partial derivatives by specifying the order of
differentiation.
}{
\spadpaste{g := sin(x**2 + y) \bound{g}}
}
\xtc{
}{
\spadpaste{D(g, y) \free{g}}
}
\xtc{
}{
\spadpaste{D(g, [y, y, x, x]) \free{g}}
}
}

Axiom can manipulate the derivatives (partial and iterated) of
expressions involving formal operators.
All the dependencies must be explicit.
\xtc{

```

This returns `\axiom{0}` since `\axiom{F}` (so far) does not explicitly depend on `\axiom{x}`.

```
{
\spadpaste{D(F,x)}
}
Suppose that we have \axiom{F} a function of \axiom{x},
\axiom{y}, and \axiom{z}, where \axiom{x} and \axiom{y} are themselves
functions of \axiom{z}.
\xtc{
Start by declaring that \axiom{F}, \axiom{x}, and \axiom{y}
are operators.
}{
\spadpaste{
F := operator 'F; x := operator 'x; y := operator 'y\bound{F x y}}
}
\xtc{
You can use \axiom{F}, \axiom{x}, and \axiom{y} in expressions.
}{
\spadpaste{
a := F(x z, y z, z**2) + x y(z+1) \bound{a}\free{F}\free{x}\free{y}}
}
\xtc{
Differentiate formally with respect to \axiom{z}. The formal
derivatives appearing in \axiom{dadz} are not just formal symbols, but
do represent the derivatives of \axiom{x}, \axiom{y}, and \axiom{F}.
}{
\spadpaste{dadz := D(a, z)\bound{da}\free{a}}
}
\xtc{
You can evaluate the above for particular functional values of
\axiom{F}, \axiom{x}, and \axiom{y}. If \axiom{x(z)} is
\axiom{exp(z)} and \axiom{y(z)} is \axiom{log(z+1)}, then this
evaluates \axiom{dadz}.
}{
\spadpaste{eval(eval(dadz, 'x, z +-> exp z), 'y, z +-> log(z+1))\free{da}}
}
\xtc{
You obtain the same result by first evaluating \axiom{a} and
then differentiating.
}{
\spadpaste{eval(eval(a, 'x, z +-> exp z), 'y, z +-> log(z+1)) \free{a}\bound{eva}}
}
\xtc{
}{
\spadpaste{D(\%, z)\free{eva}}
}
}

6.0.31 Integration

⇒ “notitle” (ugProblemIntegrationPage) 12.0.163 on page 2427

```
<ug01.ht>+≡
\begin{page}{ugIntroIntegratePage}{1.13. Integration}
\beginscroll
%
```

Axiom has extensive library facilities for integration.

The first example is the integration of a fraction with denominator that factors into a quadratic and a quartic irreducible polynomial. The usual partial fraction approach used by most other computer algebra systems either fails or introduces expensive unneeded algebraic numbers.

```
\xtc{
We use a factorization-free algorithm.
}{
\spadpaste{integrate((x**2+2*x+1)/((x+1)**6+1),x)}
}
```

When real parameters are present, the form of the integral can depend on the signs of some expressions.

```
\xtc{
Rather than query the user or make sign assumptions, Axiom returns
all possible answers.
}{
\spadpaste{integrate(1/(x**2 + a),x)}
}
```

The `\axiomFun{integrate}` operation generally assumes that all parameters are real.

The only exception is when the integrand has complex valued quantities.

```
\xtc{
If the parameter is complex instead of real, then the notion of sign
is undefined and there is a unique answer. You can request this
answer by ‘‘prepending’’ the word ‘‘complex’’ to the command name:
}{
\spadpaste{complexIntegrate(1/(x**2 + a),x)}
}
```

The following two examples illustrate the limitations of table-based approaches. The two integrands are very similar, but the answer to one of them requires the addition of two new algebraic numbers.

```
\xtc{
This one is the easy one.
The next one looks very similar
but the answer is much more complicated.
}{
\spadpaste{integrate(x**3 / (a+b*x)**(1/3),x)}
}
\xtc{
Only an algorithmic approach
is guaranteed to find what new constants must be added in order to
find a solution.
}{
\spadpaste{integrate(1 / (x**3 * (a+b*x)**(1/3)),x)}
}
```

Some computer algebra systems use heuristics or table-driven approaches to integration. When these systems cannot determine the answer to an integration problem, they reply ‘‘I don’t know.’’ Axiom uses an algorithm for integration. that conclusively proves that an integral cannot be expressed in terms of elementary functions.

```
\xtc{
When Axiom returns an integral sign, it has proved
that no answer exists as an elementary function.
}{
\spadpaste{integrate(log(1 + sqrt(a*x + b)) / x,x)}
}
Axiom can handle complicated mixed functions much beyond what you
can find in tables.
\xtc{
Whenever possible, Axiom tries to express the answer using the functions
present in the integrand.
}{
\spadpaste{integrate((sinh(1+sqrt(x+b))+2*sqrt(x+b)) /
(sqrt(x+b) * (x + cosh(1+sqrt(x + b))))), x)}
}
\xtc{
A strong structure-checking algorithm in Axiom finds hidden algebraic
relationships between functions.
}{
\spadpaste{integrate(tan(atan(x)/3),x)}
```

```

}
\noindent
%%--> Bob---> please make these formulas in this section smaller.
The discovery of this algebraic relationship is necessary for correct
integration of this function.
Here are the details:
\indent{4}
\beginitems
\item[1. ]
If  $x = \tan t$   $\{\text{\axiom}\{x = \tan(t)\}$  and
 $g = \tan(t/3)$   $\{\text{\axiom}\{g = \tan(t/3)\}$  then the following
algebraic relation is true:

$$g^3 - 3xg^2 - 3g + x = 0$$

\item[2. ]
Integrate  $\text{\axiom}\{g\}$  using this algebraic relation; this produces:

$$\frac{(24g^2 - 8)\log(3g^2 - 1) + (81x^2 + 24)g^2 + 72xg - 27x^2 - 16}{54g^2 - 18}$$

\item[3. ]
Rationalize the denominator, producing:

$$\frac{8\log(3g^2 - 1) - 3g^2 + 18xg + 16}{18}$$

Replace  $\text{\axiom}\{g\}$  by the initial definition
 $g = \tan(\arctan(x)/3)$   $\{\text{\axiom}\{g = \tan(\arctan(x)/3)\}$ 
to produce the final result.
\enditems
\indent{0}

\xtc{
This is an example of a mixed function where
the algebraic layer is over the transcendental one.
}{
\spadpaste{integrate((x + 1) / (x*(x + log x) ** (3/2)), x)}
}
\xtc{
While incomplete for non-elementary functions, Axiom can
handle some of them.
}{
\spadpaste{integrate(exp(-x**2) * erf(x) /
(erf(x)**3 - erf(x)**2 - erf(x) + 1), x)}
}

More examples of Axiom's integration capabilities are discussed in
\downlink{'Integration'}{ugProblemIntegrationPage}

```

in Section 8.8\ignore{ugProblemIntegration}.

6.0.32 Differential Equations

```

<ug01.ht>+≡
\begin{page}{ugIntroDiffEqnsPage}{1.14. Differential Equations}
\beginscroll
%
The general approach used in integration also carries over to the
solution of linear differential equations.

\labelSpace{2pc}
\xtc{
Let's solve some differential equations.
Let \axiom{y} be the unknown function in terms of \axiom{x}.
}{
\spadpaste{y := operator 'y \bound{y}}
}
\xtc{
Here we solve a third order equation with polynomial coefficients.
}{
\spadpaste{deq := x**3 * D(y x, x, 3) + x**2 * D(y x, x, 2) - 2 *
x * D(y x, x) + 2 * y x = 2 * x**4 \bound{e3}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{e3}\free{y}}
}
\xtc{
Here we find all the algebraic function solutions of the equation.
}{
\spadpaste{
deq := (x**2 + 1) * D(y x, x, 2) + 3 * x * D(y x, x) + y x = 0
\bound{e5}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{e5}\free{y}}
}

Coefficients of differential equations can come from arbitrary
constant fields.
For example, coefficients can contain algebraic numbers.

\xtc{
This example has solutions
whose logarithmic derivative is an algebraic function of
degree two.

```

```

}{
\spadpaste{eq := 2*x**3 * D(y x,x,2) + 3*x**2 * D(y x,x) - 2 * y x
\bound{eq}\free{y}}
}
\xtc{
}{
\spadpaste{solve(eq,y,x).basis\free{eq}}
}

```

```

\xtc{
Here's another differential equation to solve.
}{
\spadpaste{deq := D(y x, x) = y(x) / (x + y(x) * log y x)
\bound{deq}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{deq y}}
}

```

Rather than attempting to get a closed form solution of a differential equation, you instead might want to find an approximate solution in the form of a series.

```

\xtc{
Let's solve a system of nonlinear first order equations and get a
solution in power series.
Tell Axiom that \axiom{x} is also an operator.
}{
\spadpaste{x := operator 'x\bound{x}}
}
\xtc{
Here are the two equations forming our system.
}{
\spadpaste{eq1 := D(x(t), t) = 1 + x(t)**2\free{x}\free{y}\bound{eq1}}
}
\xtc{
}{
\spadpaste{eq2 := D(y(t), t) = x(t) * y(t)\free{x}\free{y}\bound{eq2}}
}
\xtc{
We can solve the system around \axiom{t = 0} with the initial conditions
\axiom{x(0) = 0} and \axiom{y(0) = 1}.
Notice that since we give the unknowns in the
order \axiom{[x, y]}, the answer is a list of two series in the order
\axiom{[series for x(t), series for y(t)]}.

```

```

}{
\spadpaste{seriesSolve([eq2, eq1], [x, y], t = 0,
[y(0) = 1, x(0) = 0])\free{x}\free{y}\free{eq1}\free{eq2}}
}

```

```

6.0.33 Solution of Equations

<ug01.ht>+≡

```
\begin{page}{ugIntroSolutionPage}{1.15. Solution of Equations}
\beginscroll
%
```

Axiom also has state-of-the-art algorithms for the solution of systems of polynomial equations.

When the number of equations and unknowns is the same, and you have no symbolic coefficients, you can use `\spadfun{solve}` for real roots and `\spadfun{complexSolve}` for complex roots.

In each case, you tell Axiom how accurate you want your result to be.

All operations in the `\spadfun{solve}` family return answers in the form of a list of solution sets, where each solution set is a list of equations.

```
\xtc{
```

A system of two equations involving a symbolic parameter `\axiom{t}`.

```
}{
```

```
\spadpaste{S(t) == [x**2-2*y**2 - t,x*y-y-5*x + 5]\bound{S1}}
```

```
}
```

```
\xtc{
```

Find the real roots of `\spad{S(19)}` with rational arithmetic, correct to within `\smath{1/10^{20}}`.

```
}{
```

```
\spadpaste{solve(S(19),1/10**20)\free{S1}}
```

```
}
```

```
\xtc{
```

Find the complex roots of `\spad{S(19)}` with floating point coefficients to `\spad{20}` digits accuracy in the mantissa.

```
}{
```

```
\spadpaste{complexSolve(S(19),10.e-20)\free{S1}}
```

```
}
```

```
\xtc{
```

If a system of equations has symbolic coefficients and you want a solution in radicals, try `\spadfun{radicalSolve}`.

```
}{
```

```
\spadpaste{radicalSolve(S(a),[x,y])\free{S1}}
```

```
}
```

For systems of equations with symbolic coefficients, you can apply `\spadfun{solve}`, listing the variables that you want Axiom to solve for. For polynomial equations, a solution cannot usually be expressed solely in terms of the other variables. Instead, the solution is

presented as a ‘‘triangular’’ system of equations, where each polynomial has coefficients involving only the succeeding variables. This is analogous to converting a linear system of equations to ‘‘triangular form’’.

```
\xctc{
A system of three equations in five variables.
}{
\spadpaste{eqns := [x**2 - y + z,x**2*z + x**4 - b*y, y**2 *z - a - b*x]
\bound{e}}
}
\xctc{
Solve the system for unknowns \smath{[x,y,z]},
reducing the solution to triangular form.
}{
\spadpaste{solve(eqns,[x,y,z])\free{e}}
}

```
<ug01.ht>+≡
\begin{page}{ugIntroSysCmmandsPage}{1.16. System Commands}
\beginscroll
%
```

We conclude our tour of Axiom with a brief discussion of `\spadgloss{system commands}`. System commands are special statements that start with a closing parenthesis (`\axiomSyntax{}`). They are used to control or display your Axiom environment, start the Hyperdoc system, issue operating system commands and leave Axiom. For example, `\spadsys{system}` is used to issue commands to the operating system from Axiom. Here is a brief description of some of these commands. For more information on specific commands, see `\downlink{‘‘Axiom System Commands’’}{ugSysCmdPage}` in Appendix B `\ignore{ugSysCmd}`.

Perhaps the most important user command is the `\spadsys{clear all}` command that initializes your environment. Every section and subsection in this book has an invisible `\spadsys{clear all}` that is read prior to the examples given in the section. `\spadsys{clear all}` gives you a fresh, empty environment with no user variables defined and the step number reset to `\axiom{1}`. The `\spadsys{clear}` command can also be used to selectively clear values and properties of system variables.

Another useful system command is `\spadsys{read}`. A preferred way to develop an application in Axiom is to put your interactive commands into a file, say `{\bf my.input}` file. To get Axiom to read this file, you use the system command `\spadsys{read my.input}`. If you need to make changes to your approach or definitions, go into your favorite editor, change `{\bf my.input}`, then `\spadsys{read my.input}` again.

Other system commands include: `\spadsys{history}`, to display previous input and/or output lines; `\spadsys{display}`, to display properties and values of workspace variables; and `\spadsys{what}`.

```
\xrc{
Issue \spadsys{what} to get a list of Axiom objects that
contain a given substring in their name.
}{
\spadpaste{what operations integrate}
```

```
}
```

```
%\head{subsection}{Undo}{ugIntroUndo}
```

A useful system command is `\spadcmd{}undo`.

Sometimes while computing interactively with Axiom, you make a mistake and enter an incorrect definition or assignment.

Or perhaps you

need to try one of several alternative approaches, one after another, to find the best way to approach an application.

For this, you will find the `\spadgloss{}undo` facility of Axiom helpful.

System command `\spadsys{}undo n` means ‘undo back to step `\axiom{n}`’; it restores the values of user variables to those that existed immediately after input expression `\axiom{n}` was evaluated. Similarly, `\spadsys{}undo -n` undoes changes caused by the last `\axiom{n}` input expressions. Once you have done an `\spadsys{}undo`, you can continue on from there, or make a change and **redo** all your input expressions from the point of the `\spadsys{}undo` forward. The `\spadsys{}undo` is completely general: it changes the environment like any user expression. Thus you can `\spadsys{}undo` any previous undo.

Here is a sample dialogue between user and Axiom.

```
\xrc{
  ‘Let me define
two mutually dependent functions \axiom{f} and \axiom{g} piece-wise.’
}{
\spadpaste{f(0) == 1; g(0) == 1\bound{u1}}
}
\xrc{
  ‘Here is the general term for \axiom{f}.’
}{
\spadpaste{f(n) == e/2*f(n-1) - x*g(n-1)\bound{u2}\free{u1}}
}
\xrc{
  ‘And here is the general term for \axiom{g}.’
}{
\spadpaste{g(n) == -x*f(n-1) + d/3*g(n-1)\bound{u3}\free{u2}}
}
\xrc{
  ‘What is value of \axiom{f(3)}?’
}{
\spadpaste{f(3)\bound{u4}\free{u3}}
}
```

```

\noOutputXtc{
  ‘‘Hmm, I think I want to define \axiom{f} differently.
  Undo to the environment right after I defined \axiom{f}.’’
}{
  \spadpaste{undo 2\bound{u5}\free{u4}}
}
\xtc{
  ‘‘Here is how I think I want \axiom{f} to be defined instead.’’
}{
  \spadpaste{f(n) == d/3*f(n-1) - x*g(n-1)\bound{u6}\free{u5}}
}
\noOutputXtc{
  Redo the computation from expression \axiom{3} forward.
}{
  \spadpaste{undo }redo\bound{u7}\free{u6}}
}
\noOutputXtc{
  ‘‘I want my old definition of
  \axiom{f} after all. Undo the undo and restore
  the environment to that immediately after \axiom{(4)}.’’
}{
  \spadpaste{undo 4\bound{u8}\free{u7}}
}
\xtc{
  ‘‘Check that the value of \axiom{f(3)} is restored.’’
}{
  \spadpaste{f(3)\bound{u9}\free{u8}}
}

```

After you have gone off on several tangents, then backtracked to previous points in your conversation using `\spadsys{}undo`, you might want to save all the ‘‘correct’’ input commands you issued, disregarding those undone. The system command `\spadsys{}history` `)write mynew.input` writes a clean straight-line program onto the file `{\bf mynew.input}` on your disk.

This concludes your tour of Axiom.

To disembark, issue the system command `\spadsys{}quit` to leave Axiom and return to the operating system.

\begin{page}{ugTypesPage}{2. Using Types and Modes}  
\beginscroll
```

In this chapter we look at the key notion of `\spadgloss{type}` and its generalization `\spadgloss{mode}`. We show that every Axiom object has a type that determines what you can do with the object. In particular, we explain how to use types to call specific functions from particular parts of the library and how types and modes can be used to create new objects from old. We also look at `\pspadtype{Record}` and `\pspadtype{Union}` types and the special type `\axiomType{Any}`. Finally, we give you an idea of how Axiom

manipulates types and modes internally to resolve ambiguities.

7.0.36 The Basic Idea

⇐ “Conversion” (ugTypesConvertPage) 7.0.50 on page 1864

⇒ “Domain Constructors” (ugTypesBasicDomainConsPage) 7.0.37 on page 1802

`<ug02.ht>+≡`

```
\begin{page}{ugTypesBasicPage}{2.1. The Basic Idea}
\beginscroll
```

The Axiom world deals with many kinds of objects.
There are mathematical objects such as numbers and polynomials,
data structure objects such as lists and arrays, and graphics
objects such as points and graphic images.
Functions are objects too.

Axiom organizes objects using the notion of \spadglossSee{domain of
computation}{domain}, or simply \spadgloss{domain}. Each domain
denotes a class of objects. The class of objects it denotes is
usually given by the name of the domain: \axiomType{Integer} for the
integers, \axiomType{Float} for floating-point numbers, and so on.
The convention is that the first letter of a domain name is
capitalized. Similarly, the domain \axiomType{Polynomial(Integer)}
denotes “polynomials with integer coefficients.” Also,
\axiomType{Matrix(Float)} denotes “matrices with floating-point
entries.”

Every basic Axiom object belongs to a unique domain. The integer `\axiom{3}` belongs to the domain `\axiomType{Integer}` and the polynomial `\axiom{x + 3}` belongs to the domain `\axiomType{Polynomial(Integer)}`. The domain of an object is also called its `\spadgloss{type}`. Thus we speak of “the type `\axiomType{Integer}`” and “the type `\axiomType{Polynomial(Integer)}`.”

`\xctc{`

After an Axiom computation, the type is displayed toward the right-hand side of the page (or screen).

`}{`

`\spadpaste{-3}`

`}`

`\xctc{`

Here we create a rational number but it looks like the last result. The type however tells you it is different.

You cannot identify the type of an object by how Axiom displays the object.

`}{`

`\spadpaste{-3/1}`

`}`

`\xctc{`

When a computation produces a result of a simpler type, Axiom leaves the type unsimplified.

Thus no information is lost.

`}{`

`\spadpaste{x + 3 - x \bound{three}}`

`}`

`\xctc{`

This seldom matters since Axiom retracts the answer to the simpler type if it is necessary.

`}{`

`\spadpaste{factorial(\%) \free{three}}`

`}`

`\xctc{`

When you issue a positive number, the type `\axiomType{PositiveInteger}` is printed. Surely, `\axiom{3}` also has type `\axiomType{Integer}`! The curious reader may now have two questions. First, is the type of an object not unique? Second, how is `\axiomType{PositiveInteger}` related to `\axiomType{Integer}`? Read on!

`}{`

`\spadpaste{3}`

`}`

Any domain can be refined to a `\spadgloss{subdomain}` by a membership `\spadgloss{predicate}`.
`\footnote{A predicate is a function that, when`

applied to an object of the domain, returns either `\axiom{true}` or `\axiom{false}`.) For example, the domain `\axiomType{Integer}` can be refined to the subdomain `\axiomType{PositiveInteger}`, the set of integers `\axiom{x}` such that `\axiom{x > 0}`, by giving the Axiom predicate `\axiom{x +-> x > 0}`. Similarly, Axiom can define subdomains such as “the subdomain of diagonal matrices,” “the subdomain of lists of length two,” “the subdomain of monic irreducible polynomials in `\axiom{x}`,” and so on. Trivially, any domain is a subdomain of itself.

While an object belongs to a unique domain, it can belong to any number of subdomains. Any subdomain of the domain of an object can be used as the `{\it type}` of that object. The type of `\axiom{3}` is indeed both `\axiomType{Integer}` and `\axiomType{PositiveInteger}` as well as any other subdomain of integer whose predicate is satisfied, such as “the prime integers,” “the odd positive integers between 3 and 17,” and so on.

```
\begin{page}{ugTypesBasicDomainConsPage}{2.1.1. Domain Constructors}
\beginscroll
```

In Axiom, domains are objects. You can create them, pass them to functions, and, as we'll see later, test them for certain properties.

In Axiom, you ask for a value of a function by applying its name to a set of arguments.

```
\xtc{
To ask for ``the factorial of 7'' you enter this expression to Axiom.
This applies the function \axiom{factorial} to the value \axiom{7} to
compute the result.
}{
\spadpaste{factorial(7)}
}
\xtc{
Enter the type \axiomType{Polynomial(Integer)} as an expression to
Axiom. This looks much like a function call as well. It is! The
```

result is appropriately stated to be of type `\axiomType{Domain}`, which according to our usual convention, denotes the class of all domains.

```
{
\spadpaste{Polynomial(Integer)}
}
```

The most basic operation involving domains is that of building a new domain from a given one. To create the domain of “polynomials over the integers,” Axiom applies the function `\axiomType{Polynomial}` to the domain `\axiomType{Integer}`. A function like `\axiomType{Polynomial}` is called a `\spadgloss{domain constructor}` or, more simply, a `\spadgloss{constructor}`. A domain constructor is a function that creates a domain. An argument to a domain constructor can be another domain or, in general, an arbitrary kind of object. `\axiomType{Polynomial}` takes a single domain argument while `\axiomType{SquareMatrix}` takes a positive integer as an argument to give its dimension and a domain argument to give the type of its components.

What kinds of domains can you use as the argument to `\axiomType{Polynomial}` or `\axiomType{SquareMatrix}` or `\axiomType{List}`? Well, the first two are mathematical in nature. You want to be able to perform algebraic operations like `\axiomOp{+}` and `\axiomOp{*}` on polynomials and square matrices, and operations such as `\axiomFun{determinant}` on square matrices. So you want to allow polynomials of integers `{\it and}` polynomials of square matrices with complex number coefficients and, in general, anything that “makes sense.” At the same time, you don’t want Axiom to be able to build nonsense domains such as “polynomials of strings!”

In contrast to algebraic structures, data structures can hold any kind of object. Operations on lists such as `\axiomFunFrom{insert}{List}`, `\axiomFunFrom{delete}{List}`, and `\axiomFunFrom{concat}{List}` just manipulate the list itself without changing or operating on its elements. Thus you can build `\axiomType{List}` over almost any datatype, including itself.

```
\xtc{
Create a complicated algebraic domain.
}{
\spadpaste{
List (List (Matrix (Polynomial (Complex (Fraction (Integer))))))}
}
\xtc{
Try to create a meaningless domain.
}{
\spadpaste{Polynomial(String)}
```

```

}
Evidently from our last example, Axiom has some mechanism
that tells what a constructor can use as an argument.
This brings us to the notion of \spadgloss{category}.
As domains are objects, they too have a domain.
The domain of a domain is a category.
A category is simply a type whose members are domains.

```

A common algebraic category is `\axiomType{Ring}`, the class of all domains that are “rings.” A ring is an algebraic structure with constants `\axiom{0}` and `\axiom{1}` and operations `\axiomOpFrom{+}{Ring}`, `\axiomOpFrom{-}{Ring}`, and `\axiomOpFrom{*}{Ring}`. These operations are assumed “closed” with respect to the domain, meaning that they take two objects of the domain and produce a result object also in the domain. The operations are understood to satisfy certain “axioms,” certain mathematical principles providing the algebraic foundation for rings. For example, the `\it additive inverse axiom` for rings states: `\centerline{{Every element \axiom{x} has an additive inverse \axiom{y} such}}`
`\centerline{{that \axiom{x + y = 0}}}` The prototypical example of a domain that is a ring is the integers. Keep them in mind whenever we mention `\axiomType{Ring}`.

Many algebraic domain constructors such as `\axiomType{Complex}`, `\axiomType{Polynomial}`, `\axiomType{Fraction}`, take rings as arguments and return rings as values. You can use the infix operator “`\axiom{has}`” `\spadkey{has}` to ask a domain if it belongs to a particular category.

```

\xtc{
All numerical types are rings. Domain constructor
\axiomType{Polynomial} builds “the ring of polynomials over any other
ring.”
}{
\spadpaste{Polynomial(Integer) has Ring}
}
\xtc{
Constructor \axiomType{List} never produces a ring.
}{
\spadpaste{List(Integer) has Ring}
}
\xtc{
The constructor \axiomType{Matrix(R)} builds “the domain of all
matrices over the ring \axiom{R}.” This domain is never a ring since
the operations \axiomSyntax{+}, \axiomSyntax{-}, and \axiomSyntax{*}
on matrices of arbitrary shapes are undefined.

```

```

}{
\spadpaste{Matrix(Integer) has Ring}
}
\xtc{
Thus you can never build polynomials over matrices.
}{
\spadpaste{Polynomial(Matrix(Integer))}
}
\xtc{
Use \axiomType{SquareMatrix(n,R)} instead.
For any positive integer \axiom{n}, it builds “the ring of \axiom{n} by
\axiom{n} matrices over \axiom{R}.”
}{
\spadpaste{Polynomial(SquareMatrix(7,Complex(Integer)))}
}

```

Another common category is `\axiomType{Field}`, the class of all fields. A field is a ring with additional operations. For example, a field has commutative multiplication and a closed operation `\axiomOpFrom{/}{Field}` for the division of two elements. `\axiomType{Integer}` is not a field since, for example, `\axiom{3/2}` does not have an integer result. The prototypical example of a field is the rational numbers, that is, the domain `\axiomType{Fraction(Integer)}`. In general, the constructor `\axiomType{Fraction}` takes a ring as an argument and returns a field.^{\footnote{Actually, the argument domain must have some additional properties so as to belong to category `\axiomType{IntegralDomain}`.}} Other domain constructors, such as `\axiomType{Complex}`, build fields only if their argument domain is a field.

```

\xtc{
The complex integers (often called the “Gaussian integers”) do not
form a field.
}{
\spadpaste{Complex(Integer) has Field}
}
\xtc{
But fractions of complex integers do.
}{
\spadpaste{Fraction(Complex(Integer)) has Field}
}
\xtc{
The algebraically equivalent domain of complex rational numbers is a
field since domain constructor \axiomType{Complex} produces a field
whenever its argument is a field.

```

```

}{
\spadpaste{Complex(Fraction(Integer)) has Field}
}

```

The most basic category is `\axiomType{Type}`. It denotes the class of all domains and subdomains.^{\footnote{\axiomType{Type} does not denote the class of all types. The type of all categories is `\axiomType{Category}`. The type of `\axiomType{Type}` itself is undefined.}} Domain constructor `\axiomType{List}` is able to build ‘‘lists of elements from domain `\axiom{D}`’’ for arbitrary `\axiom{D}` simply by requiring that `\axiom{D}` belong to category `\axiomType{Type}`.

Now, you may ask, what exactly is a category?

Like domains, categories can be defined in the Axiom language.

A category is defined by three components:

```

%
\indent{4}
\beginitems
\item[1. ] a name (for example, \axiomType{Ring}),
used to refer to the class of domains that the category represents;
\item[2. ] a set of operations, used to refer to the operations that
the domains of this class support
(for example, \axiomOp{+}, \axiomOp{-}, and \axiomOp{*} for rings); and
\item[3. ] an optional list of other categories that this category extends.
\enditems
\indent{0}
%

```

This last component is a new idea. And it is key to the design of Axiom! Because categories can extend one another, they form hierarchies. \texht{Detailed charts showing the category hierarchies in Axiom are displayed in the endpages of this book. There you see that all categories are extensions of `\axiomType{Type}` and that `\axiomType{Field}` is an extension of `\axiomType{Ring}`.}{}

The operations supported by the domains of a category are called the `\spadglossSee{exports}{export}` of that category because these are the operations made available for system-wide use. The exports of a domain of a given category are not only the ones explicitly mentioned by the category. Since a category extends other categories, the operations of these other categories---and all categories these other categories extend---are also exported by the domains.

For example, polynomial domains belong to

`\axiomType{PolynomialCategory}`. This category explicitly mentions

some twenty-nine operations on polynomials, but it extends eleven other categories (including `\axiomType{Ring}`). As a result, the current system has over one hundred operations on polynomials.

If a domain belongs to a category that extends, say, `\axiomType{Ring}`, it is convenient to say that the domain exports `\axiomType{Ring}`. The name of the category thus provides a convenient shorthand for the list of operations exported by the category. Rather than listing operations such as `\axiomOpFrom{+}{Ring}` and `\axiomOpFrom{*}{Ring}` of `\axiomType{Ring}` each time they are needed, the definition of a type simply asserts that it exports category `\axiomType{Ring}`.

The category name, however, is more than a shorthand. The name `\axiomType{Ring}`, in fact, implies that the operations exported by rings are required to satisfy a set of ‘‘axioms’’ associated with the name `\axiomType{Ring}`.^{footnote{This subtle but important feature distinguishes Axiom from other abstract datatype designs.}}

Why is it not correct to assume that some type is a ring if it exports all of the operations of `\axiomType{Ring}`? Here is why. Some languages such as `\bf APL` denote the `\axiomType{Boolean}` constants `\axiom{true}` and `\axiom{false}` by the integers `\axiom{1}` and `\axiom{0}` respectively, then use `\axiomOp{+}` and `\axiomOp{*}` to denote the logical operators `\axiomFun{or}` and `\axiomFun{and}`. But with these definitions `\axiomType{Boolean}` is not a ring since the additive inverse axiom is violated.^{footnote{There is no inverse element $\text{\axiom{a}}$ such that $\text{\axiom{1} + a = 0}$, or, in the usual terms: $\text{\axiom{true or a} = false}$.}} This alternative definition of `\axiomType{Boolean}` can be easily and correctly implemented in Axiom, since `\axiomType{Boolean}` simply does not assert that it is of category `\axiomType{Ring}`. This prevents the system from building meaningless domains such as `\axiomType{Polynomial(Boolean)}` and then wrongfully applying algorithms that presume that the ring axioms hold.

Enough on categories. To learn more about them, see [\downlink{‘‘Categories’’}{ugCategoriesPage}](#) in Chapter 12^{\ignore{ugCategories}}. We now return to our discussion of domains.

Domains `\spadgloss{export}` a set of operations to make them available for system-wide use. `\axiomType{Integer}`, for example, exports the operations `\axiomOpFrom{+}{Integer}` and `\axiomOpFrom{=}{Integer}` given by the `\spadglossSee{signatures}{signature}` `\axiomOpFrom{+}{Integer}`: `\spadsig{(Integer,Integer)}{Integer}` and `\axiomOpFrom{=}{Integer}`:

`\spadsig{(Integer,Integer)}{Boolean}`, respectively. Each of these operations takes two `\axiomType{Integer}` arguments. The `\axiomOpFrom{+}{Integer}` operation also returns an `\axiomType{Integer}` but `\axiomOpFrom{=}{Integer}` returns a `\axiomType{Boolean}`: `\axiom{true}` or `\axiom{false}`. The operations exported by a domain usually manipulate objects of the domain---but not always.

The operations of a domain may actually take as arguments, and return as values, objects from any domain. For example, `\axiomType{Fraction(Integer)}` exports the operations `\axiomOpFrom{/}{Fraction}`: `\spadsig{(Integer,Integer)}{Fraction(Integer)}` and `\axiomFunFrom{characteristic}{Fraction}`: `\spadsig{}{NonNegativeInteger}`.

Suppose all operations of a domain take as arguments and return as values, only objects from `\it other` domains. This kind of domain is what Axiom calls a `\spadgloss{package}`.

A package does not designate a class of objects at all. Rather, a package is just a collection of operations. Actually the bulk of the Axiom library of algorithms consists of packages. The facilities for factorization; integration; solution of linear, polynomial, and differential equations; computation of limits; and so on, are all defined in packages. Domains needed by algorithms can be passed to a package as arguments or used by name if they are not ‘‘variable.’’ Packages are useful for defining operations that convert objects of one type to another, particularly when these types have different parameterizations. As an example, the package `\axiomType{PolynomialFunction2(R,S)}` defines operations that convert polynomials over a domain `\axiom{R}` to polynomials over `\axiom{S}`. To convert an object from `\axiomType{Polynomial(Integer)}` to `\axiomType{Polynomial(Float)}`, Axiom builds the package `\axiomType{PolynomialFunctions2(Integer,Float)}` in order to create the required conversion function. (This happens ‘‘behind the scenes’’ for you: see `\downlink{‘‘Conversion’’}{ugTypesConvertPage}` in Section 2.7\ignore{ugTypesConvert} for details on how to convert objects.)

Axiom categories, domains and packages and all their contained functions are written in the Axiom programming language and have been compiled into machine code.

This is what comprises the Axiom `\spadgloss{library}`.

In the rest of this book we show you how to use these domains and their functions and how to write your own functions.

\beginscroll
%
```

We have already seen in `\texht{the last section}{\downlink{‘‘The Basic Idea’’}{ugTypesBasicPage}}` in Section 2.1`\ignore{ugTypesBasic}}` several examples of types. Most of these examples had either no arguments (for example, `\axiomType{Integer}`) or one argument (for example, `\axiomType{Polynomial (Integer)}`). In this section we give details about writing arbitrary types. We then define `\spadglossSee{modes}{mode}` and discuss how to write them. We conclude the section with a discussion on constructor abbreviations.

```

```

7.0.40 Types with One Argument

⇒ “notitle” (ugTypesPkgCallPage) 7.0.52 on page 1882

```
<ug02.ht>+≡
\begin{page}{ugTypesWritingOnePage}{2.2.2. Types with One Argument}
\beginscroll
```

A constructor with one argument can frequently be written with no parentheses. Types nest from right to left so that `\axiomType{Complex Fraction Polynomial Integer}` is the same as `\axiomType{Complex (Fraction (Polynomial (Integer)))}`. You need to use parentheses to force the application of a constructor to the correct argument, but you need not use any more than is necessary to remove ambiguities.

Here are some guidelines for using parentheses (they are possibly slightly more restrictive than they need to be).

```
\xctc{
If the argument is an expression like \axiom{2 + 3}
then you must enclose the argument in parentheses.
}{
\spadpaste{e : PrimeField(2 + 3)}
}
%
\xctc{
If the type is to be used with package calling
then you must enclose the argument in parentheses.
}{
\spadpaste{content(2)\$Polynomial(Integer)}
}
\xctc{
Alternatively, you can write the type without parentheses
then enclose the whole type expression with parentheses.
}{
\spadpaste{content(2)\$(Polynomial Complex Fraction Integer)}
}
\xctc{
If you supply computation target type information
(\downlink{‘‘Package Calling and Target Types’’}{ugTypesPkgCallPage}
in Section 2.9\ignore{ugTypesPkgCall})
then you should enclose the argument in parentheses.
}{
\spadpaste{(2/3)@Fraction(Polynomial(Integer))}
}
%
```

```

\xtc{
If the type itself has parentheses around it and we are
not in the case of the first example above,
then the parentheses can usually be omitted.
}{
\spadpaste{(2/3)@Fraction(Polynomial Integer)}
}
%
\xtc{
If the type is used in a declaration and the argument is a single-word
type, integer or symbol,
then the parentheses can usually be omitted.
}{
\spadpaste{(d,f,g) : Complex Polynomial Integer}
}

7.0.41 Types with More Than One Argument

```

<ug02.ht>+≡
\begin{page}{\ugTypesWritingMorePage}
{2.2.3. Types with More Than One Argument}
\beginscroll

If a constructor
has more than
one argument, you must use parentheses.
Some examples are
\centerline{{\axiomType{UnivariatePolynomial(x, Float)}} }}
\centerline{{\axiomType{MultivariatePolynomial([z,w,r], Complex Float)}} }}
\centerline{{\axiomType{SquareMatrix(3, Integer)}} }}
\centerline{{\axiomType{FactoredFunctions2(Integer,Fraction Integer)}}}}

\endscroll
\autobuttons
\end{page}

```

7.0.42 Modes

⇒ “notitle” (ugTypesDeclarePage) 7.0.44 on page 1829

⇒ “notitle” (ugTypesConvertPage) 7.0.50 on page 1864

ug02.ht+≡

```
\begin{page}{ugTypesWritingModesPage}{2.2.4. Modes}
\beginscroll
```

A `\spadgloss{mode}` is a type that possibly is a question mark (`\axiomSyntax{?}`) or contains one in an argument position.

For example, the following are all modes.

```
\texht{
\centerline{{\begin{tabular}{ccc}}}
\centerline{{\axiomType{?} & \quad & }}
\centerline{{\axiomType{Polynomial ?} }}
\centerline{{\axiomType{Matrix Polynomial ?} & \quad & }}
\centerline{{\axiomType{SquareMatrix(3,?)} }}
\centerline{{\axiomType{Integer} & \quad & }}
\centerline{{\axiomType{OneDimensionalArray(Float)}}}}
\centerline{{\end{tabular}}}}
}{
\centerline{{\axiomType{?} }}
\centerline{{\axiomType{Polynomial ?} }}
\centerline{{\axiomType{Matrix Polynomial ?} }}
\centerline{{\axiomType{SquareMatrix(3,?)} }}
\centerline{{\axiomType{Integer} }}
\centerline{{\axiomType{OneDimensionalArray(Float)}}}}
}
```

As is evident from these examples, a mode is a type with a part that is not specified (indicated by a question mark). Only one `\axiomSyntax{?}` is allowed per mode and it must appear in the most deeply nested argument that is a type. Thus

`\nonLibAxiomType{?(Integer)}`, `\nonLibAxiomType{Matrix(? (Polynomial))}`, `\nonLibAxiomType{SquareMatrix(? , Integer)}` and `\nonLibAxiomType{SquareMatrix(? , ?)}` are all invalid. The question mark must take the place of a domain, not data (for example, the integer that is the dimension of a square matrix). This rules out, for example, the two `\axiomType{SquareMatrix}` expressions.

Modes can be used for declarations

(`\downlink{‘‘Declarations’’}{ugTypesDeclarePage}`
in Section 2.3\ignore{ugTypesDeclare}) and conversions

(\downlink{‘‘Conversion’’}{ugTypesConvertPage}
in Section 2.7\ignore{ugTypesConvert}).

However, you cannot use a mode for package calling or giving target
type information.

\endscroll
\autobuttons
\end{page}

7.0.43 Abbreviations

⇒ “notitle” (ugSysCmdwhatPage) 19.0.295 on page 2934

`<ug02.ht>+≡`

```
\begin{page}{ugTypesWritingAbbrPage}{2.2.5. Abbreviations}
\beginscroll
```

Every constructor has an abbreviation that you can freely substitute for the constructor name. In some cases, the abbreviation is nothing more than the capitalized version of the constructor name.

```
\beginImportant
```

Aside from allowing types to be written more concisely, abbreviations are used by Axiom to name various system files for constructors (such as library filenames, test input files and example files).

Here are some common abbreviations.

```
\texht{}{\table{
{\axiomType{COMPLEX}      abbreviates \axiomType{Complex}      }
{\axiomType{DFLOAT}       abbreviates \axiomType{DoubleFloat}   }
{\axiomType{EXPR}         abbreviates \axiomType{Expression}    }
{\axiomType{FLOAT}        abbreviates \axiomType{Float}         }
{\axiomType{FRAC}         abbreviates \axiomType{Fraction}      }
{\axiomType{INT}          abbreviates \axiomType{Integer}       }
{\axiomType{MATRIX}       abbreviates \axiomType{Matrix}        }
{\axiomType{NNI}          abbreviates \axiomType{NonNegativeInteger} }
{\axiomType{PI}           abbreviates \axiomType{PositiveInteger} }
{\axiomType{POLY}         abbreviates \axiomType{Polynomial}     }
{\axiomType{STRING}       abbreviates \axiomType{String}        }
{\axiomType{UP}           abbreviates \axiomType{UnivariatePolynomial} }
}}
\endImportant
```

You can combine both full constructor names and abbreviations in a type expression.

Here are some types using abbreviations.

```
\centerline{{\axiomType{POLY INT}} is the same as
\axiomType{Polynomial(INT)}} }
\centerline{{\axiomType{POLY(Integer)}} is the same
as \axiomType{Polynomial(Integer)}} }
\centerline{{\axiomType{POLY(Integer)}} is the same
as \axiomType{Polynomial(INT)}} }
\centerline{{\axiomType{FRAC(COMPLEX(INT))}} is the
same as \axiomType{Fraction Complex Integer}} }
```

`\centerline{{\axiomType{FRAC(COMPLEX(INT))}} is the
same as \axiomType{FRAC(Complex Integer)} }}`

There are several ways of finding the names of constructors and their abbreviations. For a specific constructor, use `\spadcmd{abbreviation query}`. You can also use the `\spadcmd{what}` system command to see the names and abbreviations of constructors. For more information about `\spadcmd{what}`, see

`\downlink{''what''}{ugSysCmdwhatPage}` in Section B.28

`\ignore{ugSysCmdwhat}`.

`\xctc{
\spadcmd{abbreviation query}` can be
abbreviated (no pun intended) to `\spadcmd{abb q}`.

`{
\spadpaste{abb q Integer}
}`

`\xctc{
The \spadcmd{abbreviation query} command lists
the constructor name if you give the abbreviation.
Issue \spadcmd{abb q} if you want to see the names and abbreviations
of all Axiom constructors.`

`{
\spadpaste{abb q DMP}
}`

`\xctc{
Issue this to see all packages whose names contain the string ``ode``.
{
\spadpaste{what packages ode}
}`

7.0.44 Declarations

- ⇒ “notitle” (ugLangAssignPage) 9.0.75 on page 1952
- ⇒ “notitle” (ugUserDeclarePage) 10.0.99 on page 2061
- ⇒ “notitle” (ugTypesConvertPage) 7.0.50 on page 1864
- ⇒ “notitle” (ugIntroAssignPage) 6.0.16 on page 1662

(ug02.ht)+≡

```
\begin{page}{ugTypesDeclarePage}{2.3. Declarations}
\beginscroll
```

```
%
```

A `\spadgloss{declaration}` is an expression used to restrict the type of values that can be assigned to variables. A colon (`\axiomSyntax{:}`) is always used after a variable or list of variables to be declared.

```
\beginImportant
```

For a single variable, the syntax for declaration is `\centerline{{\it variableName \axiom{:} typeOrMode}}}` For multiple variables, the syntax is `\centerline{{\tt (\subscriptIt{variableName}{1}, \subscriptIt{variableName}{2}, \ldots \subscriptIt{variableName}{N}): {\it typeOrMode}}}`

```
\endImportant
```

You can always combine a declaration with an assignment.

When you do, it is equivalent to first giving a declaration statement, then giving an assignment.

For more information on assignment, see

`\downlink{‘‘Symbols, Variables, Assignments, and Declarations’’}`
`{ugIntroAssignPage}` in Section 1.3.4\ignore{ugIntroAssign} and
`\downlink{‘‘Immediate and Delayed Assignments’’}`{ugLangAssignPage}
in Section 5.1\ignore{ugLangAssign}.

To see how to declare your own functions, see

`\downlink{‘‘Declaring the Type of Functions’’}`{ugUserDeclarePage}
in Section 6.4\ignore{ugUserDeclare}.

7.0.45 Records

```

<ug02.ht>+≡
\begin{page}{ugTypesRecordsPage}{2.4. Records}
\beginscroll
%
A \pspadtype{Record} is an object composed of one or more other objects,
each of which is referenced
with
a \spadgloss{selector}.
Components can all belong to the same type or each can have a different
type.

\beginImportant
The syntax for writing a \pspadtype{Record} type is \centerline{{{ \tt
Record(\subscriptIt{selector}{1}:\subscriptIt{type}{1},
\subscriptIt{selector}{2}:\subscriptIt{type}{2}, \ldots,
\subscriptIt{selector}{N}:\subscriptIt{type}{N})}}} You must be
careful if a selector has the same name as a variable in the
workspace. If this occurs, precede the selector name by a single
quote.
\endImportant

Record components are implicitly ordered. All the components of a
record can be set at once by assigning the record a bracketed
\spadgloss{tuple} of values of the proper length (for example,
\axiom{r : Record(a: Integer, b: String) := [1, "two"]}). To access a
component of a record \axiom{r}, write the name \axiom{r}, followed by
a period, followed by a selector.

%
\xtc{
The object returned by this computation is a record with two components: a
\axiom{quotient} part and a \axiom{remainder} part.
}{
\spadpaste{u := divide(5,2) \bound{u}}
}
%
\xtc{
This is the quotient part.
}{
\spadpaste{u.quotient \free{u}}
}
\xtc{
This is the remainder part.
}{

```

```

\spadpaste{u.remainder \free{u}}
}
%
\xtc{
You can use selector expressions on the left-hand side of an assignment
to change destructively the components of a record.
}{
\spadpaste{u.quotient := 8978 \free{u}\bound{u1}}
}
\xtc{
The selected component \axiom{quotient} has the value \axiom{8978},
which is what is returned by the assignment.
Check that the value of \axiom{u} was modified.
}{
\spadpaste{u \free{u}\free{u1}}
}
\xtc{
Selectors are evaluated.
Thus you can use variables that evaluate to selectors instead of the
selectors themselves.
}{
\spadpaste{s := 'quotient \bound{s}}
}
\xtc{
Be careful!
A selector could have the same name as a variable in the workspace.
If this occurs, precede the selector name by a single quote, as in
\axiom{u.'quotient}.
}{
\spadpaste{divide(5,2).s \free{s}}
}
\xtc{
Here we declare that the value of \axiom{bd}
has two components: a string,
to be accessed via \axiom{name}, and an integer,
to be accessed via \axiom{birthdayMonth}.
}{
\spadpaste{bd : Record(name : String, birthdayMonth : Integer)
\bound{bddec}}
}
\xtc{
You must initially set the value of the entire \pspadtype{Record}
at once.
}{
\spadpaste{bd := ["Judith", 3] \free{bddec}\bound{bd}}
}

```

```

\xtc{
Once set, you can change any of the individual components.
}{
\spadpaste{bd.name := "Katie" \free{bd}}
}
\xtc{
Records may be nested and the selector names can be shared at
different levels.
}{
\spadpaste{r : Record(a : Record(b: Integer, c: Integer), b: Integer)
\bound{rdec}}
}
\xtc{
The record \axiom{r} has a \axiom{b} selector at two different levels.
Here is an initial value for \axiom{r}.
}{
\spadpaste{r := [[1,2],3] \bound{r}\free{rdec}}
}
\xtc{
This extracts the \axiom{b} component from the \axiom{a} component of
\axiom{r}.
}{
\spadpaste{r.a.b \free{r}}
}
\xtc{
This extracts the \axiom{b} component from \axiom{r}.
}{
\spadpaste{r.b \free{r}}
}
%
\xtc{
You can also use spaces or parentheses to refer to \pspadtype{Record}
components.
This is the same as \axiom{r.a}.
}{
\spadpaste{r(a) \free{r}}
}
\xtc{
This is the same as \axiom{r.b}.
}{
\spadpaste{r b \free{r}}
}
\xtc{
This is the same as \axiom{r.b := 10}.
}{
\spadpaste{r(b) := 10 \free{r}\bound{r1}}
}

```

```

}
\xtc{
Look at \axiom{r} to make sure it was modified.
}{
\spadpaste{r \free{r1}}
}

7.0.47 Unions Without Selectors

(ug02.ht)+≡

```
\begin{page}{ugTypesUnionsW0SelPage}{2.5.1. Unions Without Selectors}
\beginscroll
```

The declaration `\axiom{x : Union(Integer, String, Float)}` states that `\axiom{x}` can have values that are integers, strings or “big” floats.

If, for example, the `\pspadtype{Union}` object is an integer, the object is said to belong to the `\axiomType{Integer}` {it branch} of the `\pspadtype{Union}`.\footnote{

Note that we are being a bit careless with the language here.

Technically, the type of `\axiom{x}` is always

`\pspadtype{Union(Integer, String, Float)}`.

If it belongs to the `\axiomType{Integer}` branch, `\axiom{x}` may be converted to an object of type `\axiomType{Integer}`.)

```
\beginImportant
```

The syntax for writing a `\pspadtype{Union}` type without selectors is `\centerline{{{ \tt Union(\subscriptIt{type}{1}, \subscriptIt{type}{2}, \ldots, \subscriptIt{type}{N})}}}` The types in a union without selectors must be distinct.

```
\endImportant
```

It is possible to create unions like

`\pspadtype{Union(Integer, PositiveInteger)}` but they are difficult to work with because of the overlap in the branch types.

See below for the rules Axiom uses for converting something into a union object.

The `\axiom{case}` infix

```
\spadkey{case}
```

operator returns a `\axiomType{Boolean}`

and can be used to determine the branch in which an object lies.

```
\xtc{
```

This function displays a message stating in which

branch of the `\pspadtype{Union}` the object (defined as `\axiom{x}` above) lies.

```
}{
```

```
\begin{spadsrc}[\bound{sayBranch}]
```

```
sayBranch(x : Union(Integer,String,Float)) : Void ==
```

```
output
```

```
  x case Integer => "Integer branch"
```

```

        x case String => "String branch"
        "Float branch"
\end{spadsrc}
}
%
\xtc{
This tries \userfun{sayBranch} with an integer.
}{
\spadpaste{sayBranch 1 \free{sayBranch}}
}
\xtc{
This tries \userfun{sayBranch} with a string.
}{
\spadpaste{sayBranch "hello" \free{sayBranch}}
}
\xtc{
This tries \userfun{sayBranch} with a floating-point number.
}{
\spadpaste{sayBranch 2.718281828 \free{sayBranch}}
}
%

```

There are two things of interest about this particular example to which we would like to draw your attention.

\indent{4}

\beginitems

\item[1.] Axiom normally converts a result to the target value before passing it to the function. If we left the declaration information out of this function definition then the \axiom{sayBranch} call would have been attempted with an \axiomType{Integer} rather than a \pspadtype{Union}, and an error would have resulted.

\item[2.] The types in a \pspadtype{Union} are searched in the order given. So if the type were given as

```

\noindent
{\small\axiom{sayBranch(x: Union(String,Integer,Float,Any)): Void}}

```

```

\noindent
then the result would have been ‘‘String branch’’ because there
is a conversion from \axiomType{Integer} to \axiomType{String}.
\enditems
\indent{0}

```

Sometimes \pspadtype{Union} types can have extremely

long names.

Axiom therefore abbreviates the names of unions by printing the type of the branch first within the `\spadtype{Union}` and then eliding the remaining types with an ellipsis (`\axiomSyntax{...}`).

```
\xctc{
Here the \axiomType{Integer} branch is displayed first.
Use \axiomSyntax{::} to create a \spadtype{Union} object from an object.
}{
\spadpaste{78 :: Union(Integer,String)}
}
\xctc{
Here the \axiomType{String} branch is displayed first.
}{
\spadpaste{s := "string" :: Union(Integer,String) \bound{s}}
}
\xctc{
Use \axiom{typeOf} to see the full and actual \spadtype{Union} type.
\spadkey{typeOf}
}{
\spadpaste{typeOf s}
}
\xctc{
A common operation that returns a union is \axiomFunFrom{exquo}{Integer}
which returns the ‘‘exact quotient’’ if the quotient is exact,...
}{
\spadpaste{three := exquo(6,2) \bound{three}}
}
\xctc{
and \axiom{"failed"} if the quotient is not exact.
}{
\spadpaste{exquo(5,2)}
}
\xctc{
A union with a \axiom{"failed"} is frequently used to indicate the failure
or lack of applicability of an object.
As another example, assign an integer a variable \axiom{r} declared to be a
rational number.
}{
\spadpaste{r: FRAC INT := 3 \bound{r}\bound{rdec}}
}
\xctc{
The operation \axiomFunFrom{retractIfCan}{Fraction} tries to retract the
fraction to the underlying domain \axiomType{Integer}.
It produces a union object.
Here it succeeds.
```

```

}{
\spadpaste{retractIfCan(r) \free{r}}
}
\xtc{
Assign it a rational number.
}{
\spadpaste{r := 3/2 \bound{r1}\free{rdec}}
}
\xtc{
Here the retraction fails.
}{
\spadpaste{retractIfCan(r) \free{r1}}
}

7.0.48 Unions With Selectors

⇒ “notitle” (ugTypesRecordsPage) 7.0.45 on page 1837

⇒ “notitle” (ugTypesUnionsWOSelPage) 7.0.47 on page 1847

`<ug02.ht>+≡`

```
\begin{page}{ugTypesUnionsWOSelPage}{2.5.2. Unions With Selectors}
\beginscroll
```

Like records (`\downlink{‘‘Records’’}{ugTypesRecordsPage}` in Section 2.4`\ignore{ugTypesRecords}`), you can write `\pspadtype{Union}` types with selectors.

```
\beginImportant
```

The syntax for writing a `\pspadtype{Union}` type with selectors is

```
\centerline{{{ \tt
```

```
Union(\subscriptIt{selector}{1}:\subscriptIt{type}{1},
\subscriptIt{selector}{2}:\subscriptIt{type}{2}, \ldots,
\subscriptIt{selector}{N}:\subscriptIt{type}{N}})} You must be
careful if a selector has the same name as a variable in the
workspace. If this occurs, precede the selector name by a single
quote. It is an error to use a selector that does not correspond to
the branch of the \pspadtype{Union} in which the element actually
lies.
```

```
\endImportant
```

Be sure to understand the difference between records and unions with selectors. Records can have more than one component and the selectors are used to refer to the components. Unions always have one component but the type of that one component can vary. An object of type `\pspadtype{Record(a: Integer, b: Float, c: String)}` contains an integer `{\it and}` a float `{\it and}` a string. An object of type `\pspadtype{Union(a: Integer, b: Float, c: String)}` contains an integer `{\it or}` a float `{\it or}` a string.

Here is a version of the `\userfun{sayBranch}` function (cf.

```
\downlink{‘‘Unions Without Selectors’’}{ugTypesUnionsWOSelPage}
```

in Section 2.5.1`\ignore{ugTypesUnionsWOSel}`)

that works with a union with selectors.

It displays a message stating in which branch of the `\pspadtype{Union}` the object lies.

```
\begin{verbatim}
```

```
sayBranch(x:Union(i:Integer,s:String,f:Float)):Void==
```

```
output
```

```
  x case i => "Integer branch"
```

```

      x case s => "String branch"
      "Float branch"
\end{verbatim}
Note that \axiom{case} uses the selector name as its right-hand argument.
\spadkey{case}
If you accidentally use the branch type on the right-hand side of
\axiom{case}, \axiom{false} will be returned.

\xtc{
Declare variable \axiom{u} to have a union type with selectors.
}{
\spadpaste{u : Union(i : Integer, s : String) \bound{undec}}
}

7.0.49 The “Any” Domain

<ug02.ht>+≡

```
\begin{page}{ugTypesAnyNonePage}{2.6. The ‘‘Any’’ Domain}
\beginscroll
```

With the exception of objects of type `\spadtype{Record}`, all Axiom data structures are homogenous, that is, they hold objects all of the same type.

If you need to get around this, you can use type `\axiomType{Any}`.

Using `\axiomType{Any}`, for example, you can create lists whose elements are integers, rational numbers, strings, and even other lists.

```
\xctc{
Declare \axiom{u} to have type \axiomType{Any}.
}{
\spadpaste{u: Any\bound{uany}}
}
\xctc{
Assign a list of mixed type values to \axiom{u}
}{
\spadpaste{u := [1, 7.2, 3/2, x**2, "wally"]\free{uany}\bound{u}}
}
\xctc{
When we ask for the elements, Axiom displays these types.
}{
\spadpaste{u.1 \free{u}}
}
\xctc{
Actually, these objects belong to \axiomType{Any} but Axiom
automatically converts them to their natural types for you.
}{
\spadpaste{u.3 \free{u}}
}
\xctc{
Since type \axiomType{Any} can be anything,
it can only belong to type \axiomType{Type}.
Therefore it cannot be used in algebraic domains.
}{
\spadpaste{v : Matrix(Any)}
}
```

Perhaps you are wondering how Axiom internally represents objects of type `\axiomType{Any}`.

An object of type `\axiomType{Any}` consists not only a data part representing its normal value, but also a type part (a `\it badge`) giving

its type.

For example, the value `\axiom{1}` of type `\axiomType{PositiveInteger}` as an object of type `\axiomType{Any}` internally looks like `\axiom{[1,\axiomType{PositiveInteger()}]}`.

%When should you use `\axiomType{Any}` instead of a `\pspadtype{Union}` type?
 %Can you plan ahead?
 %For a `\pspadtype{Union}`, you must know in advance exactly which types you
 %are
 %\index{union!vs. Any@{vs. \protect\nonLibAxiomType{Any}}}
 %going to allow.
 %For `\axiomType{Any}`, anything that comes along can be accommodated.

`\beginscroll`

`%`

`\beginImportant`

`\spadglossSee{Conversion}{conversion}`

`is the process of changing an object of one type`
`into an object of another type.`

`The syntax for conversion is:`

`\centerline{{{ \it object } { \tt :: } { \it newType } }}`

`\endImportant`

`\xrc{`

`By default, \axiom{3} has the type \axiomType{PositiveInteger}.`

`}{`

`\spadpaste{3}`

`}`

`\xrc{`

`We can change this into an object of type \axiomType{Fraction Integer}`

`by using \axiomSyntax{::}.`

`}{`

```
\spadpaste{3 :: Fraction Integer}
}
```

A `\spadgloss{coercion}` is a special kind of conversion that Axiom is allowed to do automatically when you enter an expression. Coercions are usually somewhat safer than more general conversions. The Axiom library contains operations called `\axiomFun{coerce}` and `\axiomFun{convert}`. Only the `\axiomFun{coerce}` operations can be used by the interpreter to change an object into an object of another type unless you explicitly use a `\axiomSyntax{::}`.

By now you will be quite familiar with what types and modes look like. It is useful to think of a type or mode as a pattern for what you want the result to be.

```
\xctc{
Let's start with a square matrix of polynomials with complex rational
number coefficients.
```

```
}{
\spadpaste{m : SquareMatrix(2,POLY COMPLEX FRAC INT) \bound{mdec}}
}
```

```
\xctc{
}{
\spadpaste{
m := matrix [[x-3/4*\%i,z*y**2+1/2],[3/7*\%i*y**4 - x,12-\%i*9/5]]
\bound{m}\free{mdec}}
}
```

```
\xctc{
We first want to interchange the \axiomType{Complex} and
\axiomType{Fraction} layers.
We do the conversion by doing the interchange in the type expression.
```

```
}{
\spadpaste{m1 := m :: SquareMatrix(2,POLY FRAC COMPLEX INT)
\free{m}\bound{m1}}
}
```

```
\xctc{
Interchange the \axiomType{Polynomial} and the
\axiomType{Fraction} levels.
```

```
}{
\spadpaste{m2 := m1 :: SquareMatrix(2,FRAC POLY COMPLEX INT)
\free{m1}\bound{m2}}
}
```

```
\xctc{
Interchange the \axiomType{Polynomial} and the
\axiomType{Complex} levels.
}{
```

```
\spadpaste{m3 := m2 :: SquareMatrix(2,FRAC COMPLEX POLY INT)
\free{m2}\bound{m3}}
}
```

All the entries have changed types, although in comparing the last two results only the entry in the lower left corner looks different. We did all the intermediate steps to show you what Axiom can do.

```
\xctc{
In fact, we could have combined all these into one conversion.
}{
\spadpaste{m :: SquareMatrix(2,FRAC COMPLEX POLY INT) \free{m}}
}
```

There are times when Axiom is not be able to do the conversion in one step.

You may need to break up the transformation into several conversions in order to get an object of the desired type.

We cannot move either `\axiomType{Fraction}` or `\axiomType{Complex}` above (or to the left of, depending on how you look at it) `\axiomType{SquareMatrix}` because each of these levels requires that its argument type have commutative multiplication, whereas `\axiomType{SquareMatrix}` does not.^{footnote{\axiomType{Fraction} requires that its argument belong to the category `\axiomType{IntegralDomain}` and `\axiomType{Complex}` requires that its argument belong to `\axiomType{CommutativeRing}`. See `\downlink{‘‘The Basic Idea’’}{ugTypesBasicPage}` in Section 2.1\ignore{ugTypesBasic} for a brief discussion of categories.}}

The `\axiomType{Integer}` level did not move anywhere because it does not allow any arguments.

We also did not move the `\axiomType{SquareMatrix}` part anywhere, but we could have.

```
\xctc{
Recall that \axiom{m} looks like this.
}{
\spadpaste{m \free{m}}
}
```

```
\xctc{
If we want a polynomial with matrix coefficients rather than a matrix
with polynomial entries, we can just do the conversion.
}{
\spadpaste{m :: POLY SquareMatrix(2,COMPLEX FRAC INT) \free{m}}
}
\xctc{
```

We have not yet used modes for any conversions.
 Modes are a great shorthand for indicating the type of the
 object you want.

Instead of using the long type expression in the
 last example, we could have simply said this.

```
{
\spadpaste{m :: POLY ? \free{m}}
}
```

We can also indicate more structure if we want the entries
 of the matrices to be fractions.

```
{
\spadpaste{m :: POLY SquareMatrix(2,FRAC ?) \free{m}}
}
```

```

7.0.51 Subdomains Again

<ug02.ht>+≡

```
\begin{page}{ugTypesSubdomainsPage}{2.8. Subdomains Again}
\beginscroll
```

A `\spadgloss{subdomain}` `\axiom{S}` of a domain `\axiom{D}` is a domain consisting of

```
\indent{4}
```

```
\beginitems
```

```
\item[1. ] those elements of \axiom{D} that satisfy some
\spadgloss{predicate} (that is, a test that returns \axiom{true} or
\axiom{false}) and
```

```
\item[2. ] a subset of the operations of \axiom{D}.
```

```
\enditems
```

```
\indent{0}
```

Every domain is a subdomain of itself, trivially satisfying the membership test: `\axiom{true}`.

Currently, there are only two system-defined subdomains in Axiom that receive substantial use. `\axiomType{PositiveInteger}` and `\axiomType{NonNegativeInteger}` are subdomains of `\axiomType{Integer}`. An element `\axiom{x}` of `\axiomType{NonNegativeInteger}` is an integer that is greater than or equal to zero, that is, satisfies `\axiom{x >= 0.}` An element `\axiom{x}` of `\axiomType{PositiveInteger}` is a nonnegative integer that is, in fact, greater than zero, that is, satisfies `\axiom{x > 0.}` Not all operations from `\axiomType{Integer}` are available for these subdomains. For example, negation and subtraction are not provided since the subdomains are not closed under those operations. When you use an integer in an expression, Axiom assigns to it the type that is the most specific subdomain whose predicate is satisfied.

```
\xte{
```

```
This is a positive integer.
```

```
}{
```

```
\spadpaste{5}
```

```
}
```

```
\xte{
```

```
This is a nonnegative integer.
```

```
}{
```

```
\spadpaste{0}
```

```
}
```

```
\xte{
```

```
This is neither of the above.
```

```
}{
```

```
\spadpaste{-5}
```

```

}
\xtc{
Furthermore, unless you are assigning an integer to a declared variable
or using a conversion, any integer result has as type the most
specific subdomain.
}{
\spadpaste{(-2) - (-3)}
}
\xtc{
}{
\spadpaste{0 :: Integer}
}
\xtc{
}{
\spadpaste{x : NonNegativeInteger := 5}
}

```

When necessary, Axiom converts an integer object into one belonging to a less specific subdomain. For example, in `\axiom{3-2}`, the arguments to `\axiomOpFrom{-}{Integer}` are both elements of `\axiomType{PositiveInteger}`, but this type does not provide a subtraction operation. Neither does `\axiomType{NonNegativeInteger}`, so `\axiom{3}` and `\axiom{2}` are viewed as elements of `\axiomType{Integer}`, where their difference can be calculated. The result is `\axiom{1}`, which Axiom then automatically assigns the type `\axiomType{PositiveInteger}`.

```

\xtc{
Certain operations are very sensitive to the subdomains to which their
arguments belong.
This is an element of \axiomType{PositiveInteger}.
}{
\spadpaste{2 ** 2}
}
\xtc{
This is an element of \axiomType{Fraction Integer}.
}{
\spadpaste{2 ** (-2)}
}
\xtc{
It makes sense then that this
is a list of elements of \axiomType{PositiveInteger}.
}{
\spadpaste{[10**i for i in 2..5]}
}
What should the type of \axiom{[10**(i-1) for i in 2..5]} be?

```

On one hand, `\axiom{i-1}` is always an integer greater than zero as `\axiom{i}` ranges from `\axiom{2}` to `\axiom{5}` and so `\axiom{10**i}` is also always a positive integer.

On the other, `\axiom{i-1}` is a very simple function of `\axiom{i}`. Axiom does not try to analyze every such function over the index's range of values to determine whether it is always positive or nowhere negative.

For an arbitrary Axiom function, this analysis is not possible.

```
\xtc{
So, to be consistent no such analysis is done and we get this.
}{
\spadpaste{[10**(i-1) for i in 2..5]}
}
\xtc{
To get a list of elements of \axiomType{PositiveInteger} instead, you
have two choices.
You can use a conversion.
}{
\spadpaste{[10**((i-1) :: PI) for i in 2..5]}
}
\xtc{
Or you can use \axiom{pretend}.
\spadkey{pretend}
}{
\spadpaste{[10**((i-1) pretend PI) for i in 2..5]}
}
```

The operation `\axiom{pretend}` is used to defeat the Axiom type system.

The expression `\axiom{object pretend D}` means ‘‘make a new object (without copying) of type `\axiom{D}` from `\axiom{object}`.’’

If `\axiom{object}` were an integer and you told Axiom to pretend it was a list, you would probably see a message about a fatal error being caught and memory possibly being damaged. Lists do not have the same internal representation as integers!

You use `\axiom{pretend}` at your peril.

```
\xtc{
Use \axiom{pretend} with great care!
Axiom trusts you that the value is of the specified type.
}{
\spadpaste{(2/3) pretend Complex Integer}
}
```

```

<ug02.ht>+≡

```
\begin{page}{ugTypesPkgCallPage}{2.9. Package Calling and Target Types}
\beginscroll
```

Axiom works hard to figure out what you mean by an expression without your having to qualify it with type information.

Nevertheless, there are times when you need to help it along by providing hints (or even orders!) to get Axiom to do what you want.

We saw in `\downlink{‘‘Declarations’’}{ugTypesDeclarePage}` in Section 2.3 `\ignore{ugTypesDeclare}` that declarations using types and modes control the type of the results produced. For example, we can either produce a complex object with polynomial real and imaginary parts or a polynomial with complex integer coefficients, depending on the declaration.

`\spadglossSee{Package calling}{package call}` is how you tell Axiom to use a particular function from a particular part of the library.

```
\xctc{
Use the \axiomOpFrom{/}{Fraction} from \axiomType{Fraction Integer}
to create a fraction of two integers.
}{
\spadpaste{2/3}
}
\xctc{
If we wanted a floating point number, we can say ‘‘use the
\axiomOpFrom{/}{Float} in \axiomType{Float}.’’
}{
\spadpaste{(2/3)\$Float}
}
\xctc{
Perhaps we actually wanted a fraction of complex integers.
}{
\spadpaste{(2/3)\$Fraction(Complex Integer)}
}
```

In each case, Axiom used the indicated operations, sometimes first needing to convert the two integers into objects of an appropriate type.

In these examples, `\axiomOpFrom{}/{Fraction}` is written as an infix operator.

`\beginImportant`

To use package calling with an infix operator, use the following syntax:

```
\centerline{{{ \tt ( \subscriptIt{arg}{1} {\it op}
\subscriptIt{arg}{1} )\${\it type} }}}
\endImportant
```

We used, for example, `\axiom{(2/3)\$Float}`. The expression `\axiom{2 + 3 + 4}` is equivalent to `\axiom{(2+3) + 4.}` Therefore in the expression `\axiom{(2 + 3 + 4)\$Float}` the second `\axiomOp{+}` comes from the `\axiomType{Float}` domain. Can you guess whether the first `\axiomOp{+}` comes from `\axiomType{Integer}` or `\axiomType{Float}`?
`\footnote{\axiomType{Float}}`, because the package call causes Axiom to convert `\axiom{(2 + 3)}` and `\axiom{4}` to type `\axiomType{Float}`. Before the sum is converted, it is given a target type (see below) of `\axiomType{Float}` by Axiom and then evaluated. The target type causes the `\axiomOp{+}` from `\axiomType{Float}` to be used.}

`\beginImportant`

For an operator written before its arguments, you must use parentheses around the arguments (even if there is only one), and follow the closing parenthesis by a `\axiomSyntax{\$}` and then the type.

```
\centerline{{{ \tt {\it fun} ( \subscriptIt{arg}{1},
\subscriptIt{arg}{1}, \ldots, \subscriptIt{arg}{N} )\${\it type} }}}
\endImportant
```

For example, to call the ‘‘minimum’’ function from `\axiomType{DoubleFloat}` on two integers, you could write `\axiom{min(4,89)\$DoubleFloat}`.

Another use of package calling is to tell Axiom to use a library function rather than a function you defined.

We discuss this in

`\downlink{‘‘How Axiom Determines What Function to Use’’}{ugUserUsePage}`
in Section 6.9\ignore{ugUserUse}.

Sometimes rather than specifying where an operation comes from, you just want to say what type the result should be.

We say that you provide

a
`\spadglossSee{target type}{target}` for the expression.
 Instead of using a `\axiomSyntax{\$}`, use a `\axiomSyntax{@}` to specify the requested target type.
 Otherwise, the syntax is the same.
 Note that giving a target type is not the same as explicitly doing a conversion.
 The first says ‘‘try to pick operations so that the result has such-and-such a type.’’
 The second says ‘‘compute the result and then convert to an object of such-and-such a type.’’

```
\xtc{
Sometimes it makes sense, as in this expression,
to say ‘‘choose the operations in this expression so that
the final result is a \axiomType{Float}.’’
}{
\spadpaste{(2/3)@Float}
}
```

Here we used `\axiomSyntax{@}` to say that the target type of the left-hand side was `\axiomType{Float}`.

In this simple case, there was no real difference between using `\axiomSyntax{\$}` and `\axiomSyntax{@}`. You can see the difference if you try the following.

```
\xtc{
This says to try to choose \axiomOp{+} so that the result is
a string.
Axiom cannot do this.
}{
\spadpaste{(2 + 3)@String}
}
\xtc{
This says to get the \axiomOp{+} from \axiomType{String} and apply
it to the two integers.
Axiom also cannot do this because there is no \axiomOp{+}
exported by \axiomType{String}.
}{
\spadpaste{(2 + 3)\$String}
}
(By the way, the operation \axiomFunFrom{concat}{String} or juxtaposition
is used to concatenate two strings.)
```

When we have more than one operation in an expression, the difference is even more evident.

The following two expressions show that Axiom uses the

target type to create different objects.

The `\axiomOp{+}`, `\axiomOp{*}` and `\axiomOp{**}` operations are all chosen so that an object of the correct final type is created.

```
\xrc{
This says that the operations should be chosen so
that the result is a \axiomType{Complex} object.
}{
\spadpaste{((x + y * \%i)**2)@(Complex Polynomial Integer)}
}
\xrc{
This says that the operations should be chosen so
that the result is a \axiomType{Polynomial} object.
}{
\spadpaste{((x + y * \%i)**2)@(Polynomial Complex Integer)}
}
\xrc{
What do you think might happen if we left off all
target type and package call information in this last example?
}{
\spadpaste{(x + y * \%i)**2 \bound{prevC}}
}
\xrc{
We can convert it to \axiomType{Complex} as an afterthought.
But this is more work than just saying making what we want in the first
place.
}{
\spadpaste{\% :: Complex ? \free{prevC}}
}
```

Finally, another use of package calling is to qualify fully an operation that is passed as an argument to a function.

```
\xrc{
Start with a small matrix of integers.
}{
\spadpaste{h := matrix [[8,6],[-4,9]] \bound{h}}
}
%
\xrc{
We want to produce a new matrix that has for entries the multiplicative
inverses of the entries of \axiom{h}.
One way to do this is by calling
\axiomFunFrom{map}{MatrixCategoryFunctions2} with the
\axiomFunFrom{inv}{Fraction} function from \axiomType{Fraction (Integer)}.
}{
```

[illegible]

```

7.0.53 Resolving Types

`<ug02.ht>+≡`

```
\begin{page}{ugTypesResolvePage}{2.10. Resolving Types}
\beginscroll
```

In this section we briefly describe an internal process by which Axiom determines a type to which two objects of possibly different types can be converted.

We do this to give you further insight into how Axiom takes your input, analyzes it, and produces a result.

What happens when you enter `\axiom{x + 1}` to Axiom?

Let's look at what you get from the two terms of this expression.

```
\xctc{
This is a symbolic object whose type indicates the name.
}{
\spadpaste{x}
}
\xctc{
This is a positive integer.
}{
\spadpaste{1}
}
```

There are no operations in `\axiomType{PositiveInteger}` that add positive integers to objects of type `\axiomType{Variable(x)}` nor are there any in `\axiomType{Variable(x)}`.

Before it can add the two parts, Axiom must come up with a common type to which both `\axiom{x}` and `\axiom{1}` can be converted.

We say that Axiom must `{\it resolve}` the two types into a common type.

In this example, the common type is `\axiomType{Polynomial(Integer)}`.

```
\xctc{
Once this is determined, both parts are converted into polynomials,
and the addition operation from \axiomType{Polynomial(Integer)} is used
to get the answer.
}{
\spadpaste{x + 1}
}
\xctc{
Axiom can always resolve two types: if nothing resembling
the original types can be found, then \axiomType{Any} is be used.
```

This is fine and useful in some cases.

```
{
\spadpaste{["string",3.14159]}
}
```

```
\xrc{
```

In other cases objects of type `\axiomType{Any}` can't be used by the operations you specified.

```
{
\spadpaste{"string" + 3.14159}
}
```

Although this example was contrived, your expressions may need to be qualified slightly to help Axiom resolve the types involved.

You may need to declare a few variables, do some package calling, provide some target type information or do some explicit conversions.

We suggest that you just enter the expression you want evaluated and see what Axiom does.

We think you will be impressed with its ability to ‘do what I mean.’

If Axiom is still being obtuse, give it some hints.

As you work with Axiom, you will learn where it needs a little help to analyze quickly and perform your computations.

<ug02.ht>+≡
\begin{page}{ugTypesExposePage}{2.11. Exposing Domains and Packages}
\beginscroll
```

In this section we discuss how Axiom makes some operations available to you while hiding others that are meant to be used by developers or only in rare cases.

If you are a new user of Axiom, it is likely that everything you need is available by default and you may want to skip over this section on first reading.

Every domain and package in the Axiom library is either `\spadglossSee{exposed}{expose}` (meaning that you can use its operations without doing anything special) or it is `\it hidden` (meaning you have to either package call (see `\downlink{‘‘Package Calling and Target Types’’}{ugTypesPkgCallPage}` in Section 2.9`\ignore{ugTypesPkgCall}`) the operations it contains or explicitly expose it to use the operations).

The initial exposure status for a constructor is set in the file `\bf exposed.lsp` (see the `\it Installer’s Note` for Axiom if you need to know the location of this file).

Constructors are collected together in `\it exposure groups`.

Categories are all in the exposure group `‘‘categories’’` and the bulk of the basic set of packages and domains that are exposed are in the exposure group `‘‘basic.’’`

Here is an abbreviated sample of the file (without the Lisp parentheses):

```
\begin{verbatim}
```

```
basic
      AlgebraicNumber                AN
      AlgebraGivenByStructuralConstants  ALGSC
      Any                            ANY
      AnyFunctions1                  ANY1
```

```

BinaryExpansion      BINARY
Boolean              BOOLEAN
CardinalNumber       CARD
CartesianTensor       CARTEN
Character             CHAR
CharacterClass        CCLASS
CliffordAlgebra       CLIF
Color                COLOR
Complex              COMPLEX
ContinuedFraction     CONTFRAC
DecimalExpansion      DECIMAL
...
\end{verbatim}
\begin{verbatim}
categories
  AbelianGroup        ABELGRP
  AbelianMonoid        ABELMON
  AbelianMonoidRing    AMR
  AbelianSemiGroup     ABELSG
  Aggregate            AGG
  Algebra              ALGEBRA
  AlgebraicallyClosedField ACF
  AlgebraicallyClosedFunctionSpace ACFS
  ArcHyperbolicFunctionCategory AHYP
  ...
\end{verbatim}

```

For each constructor in a group, the full name and the abbreviation is given.

There are other groups in {\bf exposed.lsp} but initially only the constructors in exposure groups ‘‘basic’’ ‘‘categories’’ ‘‘naglink’’ and ‘‘anna’’ are exposed.

As an interactive user of Axiom, you do not need to modify this file. Instead, use \spadcmd{}set expose{} to expose, hide or query the exposure status of an individual constructor or exposure group. The reason for having exposure groups is to be able to expose or hide multiple constructors with a single command. For example, you might group together into exposure group ‘‘quantum’’ a number of domains and packages useful for quantum mechanical computations. These probably should not be available to every user, but you want an easy way to make the whole collection visible to Axiom when it is looking for operations to apply.

If you wanted to hide all the basic constructors available by default, you would issue \spadcmd{}set expose drop group basic{}. If, however, you discover that you have hidden all the basic constructors, you

should issue `\spadcmd{}set expose add group basic}` to restore your default environment.

It is more likely that you would want to expose or hide individual constructors. In `\downlink{'A Famous Triangle'}{ugUserTrianglePage}` in Section 6.19 `\ignore{ugUserTriangle}` we use several operations from `\axiomType{OutputForm}`, a domain usually hidden. To avoid package calling every operation from `\axiomType{OutputForm}`, we expose the domain and let Axiom conclude that those operations should be used. Use `\spadcmd{}set expose add constructor}` and `\spadcmd{}set expose drop constructor}` to expose and hide a constructor, respectively. You should use the constructor name, not the abbreviation. The `\spadcmd{}set expose}` command guides you through these options.

If you expose a previously hidden constructor, Axiom exhibits new behavior (that was your intention) though you might not expect the results that you get. `\axiomType{OutputForm}` is, in fact, one of the worst offenders in this regard. This domain is meant to be used by other domains for creating a structure that Axiom knows how to display. It has functions like `\axiomOpFrom{+}{OutputForm}` that form output representations rather than do mathematical calculations. Because of the order in which Axiom looks at constructors when it is deciding what operation to apply, `\axiomType{OutputForm}` might be used instead of what you expect. `\xtc{ This is a polynomial. }{ \spadpaste{x + x} } \xtc{ Expose \axiomType{OutputForm}. }{ \spadpaste{}set expose add constructor OutputForm \bound{setexposeadd}} } \xtc{ This is what we get when \axiomType{OutputForm} is automatically available. }{ \spadpaste{x + x \free{setexposeadd}} } \xtc{ Hide \axiomType{OutputForm} so we don't run into problems with any later examples! }{ \spadpaste{}set expose drop constructor OutputForm \bound{setexposedrop}} }`

Finally, exposure is done on a frame-by-frame basis. A `\spadgloss{frame}` (see `\downlink{'')frame'}{ugSysCmdframePage}` in Section B.11 `\ignore{ugSysCmdframe}`) is one of possibly several logical Axiom workspaces within a physical one, each having its own environment (for example, variables and function definitions). If you have several Axiom workspace windows on your screen, they are all different frames, automatically created for you by Hyperdoc. Frames can be manually created, made active and destroyed by the `\spadcmd{}frame}` system command. They do not share exposure information, so you need to use `\spadcmd{}set expose}` in each one to add or drop constructors from view.

7.0.55 Commands for Snooping

- ⇒ “notitle” (ugBrowsePage) 17.0.244 on page 2793
- ⇒ “notitle” (ComplexXmpPage) 3.16.1 on page 250
- ⇒ “notitle” (ugUserDeclarePage) 10.0.99 on page 2061

```

\ug02.ht)+≡
\begin{page}{ugAvailSnoopPage}{2.12. Commands for Snooping}
\beginscroll

```

To conclude this chapter, we introduce you to some system commands that you can use for getting more information about domains, packages, categories, and operations.

The most powerful Axiom facility for getting information about constructors and operations is the `\Browse{}` component of Hyperdoc. This is discussed in `\downlink{‘‘Browse’’}{ugBrowsePage}` in Chapter 14`\ignore{ugBrowse}`.

Use the `\spadsys{what}` system command to see lists of system objects whose name contain a particular substring (uppercase or lowercase is not significant).

```

\xtc{
Issue this to see a list of all operations with
‘‘{\tt complex}’’ in their names.
}{
\spadpaste{what operation complex}
}
\xtc{
If you want to see all domains with ‘‘{\tt matrix}’’ in their names, issue
this.
}{
\spadpaste{what domain matrix}
}
\xtc{
Similarly, if you wish to see all packages whose names contain
‘‘{\tt gauss}’’, enter this.
}{
\spadpaste{what package gauss}
}
\xtc{
This command shows all
the operations that \axiomType{Any} provides.
Wherever \axiomSyntax{\$} appears, it means ‘‘\axiomType{Any}’’.
}{

```

```

\spadpaste{show Any}
}
\xtc{
This displays all operations with the name \axiomFun{complex}.
}{
\spadpaste{display operation complex}
}
Let's analyze this output.
\xtc{
First we find out what some of the abbreviations mean.
}{
\spadpaste{abbreviation query COMPCAT}
}
\xtc{
}{
\spadpaste{abbreviation query COMRING}
}

```

So if `\axiom{D1}` is a commutative ring (such as the integers or floats) and `\axiom{D}` belongs to `\axiomType{ComplexCategory D1}`, then there is an operation called `\axiomFun{complex}` that takes two elements of `\axiom{D1}` and creates an element of `\axiom{D}`.

The primary example of a constructor implementing domains belonging to `\axiomType{ComplexCategory}` is `\axiomType{Complex}`.

See `\downlink{'Complex'}{ComplexXmpPage}\ignore{Complex}`

for more information on that and see

`\downlink{'Declaring the Type of Functions'}{ugUserDeclarePage}` in Section 6.4 `\ignore{ugUserDeclare}`

for more information on function types.

`<ug03.ht>≡
 \begin{page}{ugHyperPage}{3. Using Hyperdoc}
 \beginscroll`

Hyperdoc is the gateway to Axiom.
It's both an on-line tutorial and an on-line reference manual.
It also enables you to use Axiom simply by using the mouse and
filling in templates.
Hyperdoc is available to you if you are running Axiom under the
X Window System.

Pages usually have active areas, marked in
`\texht{{\bf this font} (bold face).}{\downlink{this font.}{YouTriedIt}}`
As you move the mouse pointer to an active area, the pointer changes from

a filled dot to an open circle.

The active areas are usually linked to other pages.

When you click on an active area, you move to the linked page.

`\texht{}{Try clicking \downlink{here}{YouTriedIt} now.}`

We suggest that you learn more about other features of

Hyperdoc by clicking on an active area in the menu below.

```
\beginmenu
  \menudownlink{{3.1. Headings}}{ugHyperHeadingsPage}
  \menudownlink{{3.2. Key Definitions}}{ugHyperKeysPage}
  \menudownlink{{3.3. Scroll Bars}}{ugHyperScrollPage}
  \menudownlink{{3.4. Input Areas}}{ugHyperInputPage}
  \menudownlink{{3.5. Radio Buttons and Toggles}}{ugHyperButtonsPage}
  \menudownlink{{3.6. Search Strings}}{ugHyperSearchPage}
  \menudownlink{{3.7. Example Pages}}{ugHyperExamplePage}
  \menudownlink{{3.8. X Window Resources for Hyperdoc}}

8.0.57 Headings

```

<ug03.ht>+≡
\begin{page}{ugHyperHeadingsPage}{3.1. Headings}
\beginscroll
%
Most pages have a standard set of buttons at the top of the page.
This is what they mean:

\indent{0}
\beginitems
\item[\StdHelpButton{}] Click on this to get help.
The button only appears if there is specific help for the page you are
viewing.
You can get {\it general} help for Hyperdoc by clicking the help
button on the home page.

\item[\UpButton{}] Click here to go back one page.
By clicking on this button repeatedly, you can go back several pages and
then take off in a new direction.

\item[\ReturnButton{}] Go back to the home page, that is,
the page on which you started.
Use Hyperdoc to explore, to make forays into new topics.
Don't worry about how to get back.
Hyperdoc remembers where you came from.
Just click on this button to return.

\item[\StdExitButton{}] From the root window (the one that is
displayed when you start the system) this button leaves the Hyperdoc
program, and it must be restarted if you want to use it again. From
any other Hyperdoc window, it just makes that one window go away. You
{\it must} use this button to get rid of a window. If you use the
window manager "Close" button, then all of Hyperdoc goes away.
\enditems
\indent{0}
%
The buttons are not displayed if they are not applicable to the page
you are viewing.
For example, there is no \ReturnButton{} button on the top-level menu.

8.0.59 Scroll Bars

⇒ “notitle” (ugHyperInputPage) 8.0.60 on page 1911

```
<ug03.ht>+≡
\begin{page}{ugHyperScrollPage}{3.3. Scroll Bars}
\beginscroll
```

Whenever there is too much text to fit on a page, a `{\it scroll bar}` automatically appears along the right side.

With a scroll bar, your page becomes an aperture, that is, a window into a larger amount of text than can be displayed at one time.

The scroll bar lets you move up and down in the text to see different parts.

It also shows where the aperture is relative to the whole text. The aperture is indicated by a strip on the scroll bar.

Move the cursor with the mouse to the “down-arrow” at the bottom of the scroll bar and click.

See that the aperture moves down one line.

Do it several times.

Each time you click, the aperture moves down one line.

Move the mouse to the “up-arrow” at the top of the scroll bar and click.

The aperture moves up one line each time you click.

Next move the mouse to any position along the middle of the scroll bar and click. Hyperdoc attempts to move the top of the aperture to this point in the text.

You cannot make the aperture go off the bottom edge. When the aperture is about half the size of text, the lowest you can move the aperture is halfway down.

To move up or down one screen at a time, use the

`\texht{\fbox{\bf PageUp}}{\fbox{\bf PageUp}}` and `\texht{\fbox{\bf PageDown}}{\fbox{\bf PageDown}}` keys on your keyboard. They move the visible part of the region up and down one page each time you press them.

If the Hyperdoc page does not contain an input area (see `\downlink{‘Input Areas’}{ugHyperInputPage}` in Section 3.4\ignore{ugHyperInput}),

you can also use the
`\texht{\fbox{\bf Home}}{\bf Home}` and
`\texht{\fbox{\uparrow}}{up}` and
`\texht{\fbox{\downarrow}}{down}` arrow keys to navigate.
When you press the `\texht{\fbox{\bf Home}}{\bf Home}` key,
the screen is positioned at the very top of the page.
Use the `\texht{\fbox{\uparrow}}{up}` and
`\texht{\fbox{\downarrow}}{down}` arrow keys to move the screen up
and down one line at a time, respectively.

```
\endscroll  
\autobuttons  
\end{page}
```

8.0.60 Input Areas

```

<ug03.ht>+≡
\begin{page}{ugHyperInputPage}{3.4. Input Areas}
\beginscroll
%
Input areas are boxes where you can put data.
Here is one:
\centerline{\inputstring{one}{40}{some text}}
\newline
As you can see, the input area has some initial text {\it some text}
followed by an underscore cursor (the character {\it _}).

To enter characters, first
move your mouse cursor to somewhere within the Hyperdoc page.
Characters that you type are inserted in front of the underscore.
This means that when you type characters at your keyboard, they
go into this first input area.

The input area grows to accommodate as many characters as you type.
Use the \texht{\fbox{\bf Backspace}}{\bf Backspace}
key to erase characters to the left.
To modify what you type, use the right-arrow \texht{\fbox{$\rightarrow$}}{}
and left-arrow keys \texht{\fbox{$\leftarrow$}}{} and the
keys \texht{\fbox{\bf Insert}}{\bf Insert},
\texht{\fbox{\bf Delete}}{\bf Delete},
\texht{\fbox{\bf Home}}{\bf Home} and
\texht{\fbox{\bf End}}{\bf End}.
These keys are found immediately on the right of the standard IBM keyboard.

If you press the
\texht{\fbox{\bf Home}}{\bf Home}
key, the cursor moves to the beginning of the line and if you press the
\texht{\fbox{\bf End}}{\bf End}
key, the cursor moves to the end of the line.
Pressing
\texht{\fbox{\bf Ctrl}--\fbox{\bf End}}{\bf Ctrl-End}
deletes all the text from the cursor to the end of the line.

A page may have more than one input area.
Only one input area has an underscore cursor.
When you first see a page, the top-most input area contains the
cursor.
To type information into another input area,
use the \texht{\fbox{\bf Enter}}{\bf Enter} or
\texht{\fbox{\bf Tab}}{\bf Tab} key to move

```

from one input area to another.

To move in the reverse order, use

```
\texht{\fbox{\bf Shift}--\fbox{\bf Tab}}{\bf Shift-Tab}.
```

You can also move from one input area to another using your mouse.

Notice that each input area is active. Click on one of the areas.

As you can see, the underscore cursor moves to that window.

```
\endscroll

\end{page}
```

8.0.61 Radio Buttons and Toggles

```

<ug03.ht>+≡
\begin{page}{ugHyperButtonsPage}{3.5. Radio Buttons and Toggles}
\beginscroll
%
Some pages have {\it radio buttons} and {\it toggles}.
Radio buttons are a group of buttons like those on car radios: you can
select only one at a time.
\radioboxes{sample}{\htbmfile{pick}}{\htbmfile{unpick}}
Here are three radio buttons:
\centerline{
{\em\radiobox[1]{rone}{sample}\space{}\ First one}\space{3}
{\em\radiobox[0]{rtwo}{sample}\space{}\ Second one}\space{3}
{\em\radiobox[0]{rthree}{sample}\space{}\ Third one}
}
\newline
Once you have selected a button, it appears to be inverted and
contains a checkmark.
To change the selection, move the cursor with the mouse to a
different radio button and click.
\texht{}{Try it now.}

A toggle is an independent button that displays some on/off
state.
When ‘‘on’’, the button appears to be inverted and
contains a checkmark.
When ‘‘off’’, the button is raised.
%
Unlike radio buttons, you can set a group of them any way you like.
Here are three:
\centerline{
{\em\inputbox[1]{one}{\htbmfile{pick}}{\htbmfile{unpick}}\space{}
\ First one}
\space{3}
{\em\inputbox[0]{two}{\htbmfile{pick}}{\htbmfile{unpick}}\space{}
\ Second one}
\space{3}
{\em\inputbox[1]{three}{\htbmfile{pick}}{\htbmfile{unpick}}\space{}
\ Third one}
}
\newline
To change toggle the selection, move the cursor with the mouse
to the button and click.

8.0.62 Search Strings

⇒ “notitle” (ugLogicalSearchesPage) 8.0.63 on page 1917

```

<ug03.ht>+≡
\begin{page}{ugHyperSearchPage}{3.6. Search Strings}
\beginscroll
%
A {\it search string} is used for searching some database.
To learn about search strings, we suggest that
you bring up the Hyperdoc glossary.
To do this from the top-level page of Hyperdoc:
\indent{4}
\beginitems
\item[1. ] Click on \windowlink{Reference}{TopReferencePage},
bringing up the Axiom Reference page.
\item[2. ] Click on \windowlink{Glossary}{GlossaryPage},
bringing up the glossary.
\texht{}{(You can also just click on the word ‘‘Glossary’’ in the
last sentence.)}
\enditems
\indent{0}
Once you get the window containing the glossary, move it so that
it and this window are both visible.

```

The glossary has an input area at its bottom.
 We review the various kinds of search strings
 you can enter to search the glossary.

The simplest search string is a word, for example, {\tt operation}.
 A word only matches an entry having exactly that spelling.
 Enter the word {\tt operation} into the input area above then click on
 {\bf Search}.
 As you can see, {\tt operation} matches only one entry, namely with {\tt
 operation} itself.

Normally matching is insensitive to whether the alphabetic characters
 of your search string are in uppercase or lowercase. Thus {\tt
 operation} and {\tt OperAtion} both have the same effect. %If you
 prefer that matching be case-sensitive, issue the command
 %\spadsys{set HHyperName mixedCase} command to the interpreter.

You will very often want to use the wildcard \spadSyntax{*} in your
 search string so as to match multiple entries in the list. The search
 key \spadSyntax{*} matches every entry in the list. You can also use

`\spadSyntax{*}` anywhere within a search string to match an arbitrary substring. Try `{\tt cat*}` for example: enter `{\tt cat*}` into the input area and click on `{\bf Search}`. This matches several entries.

You use any number of wildcards in a search string as long as they are not adjacent. Try search strings such as `{\tt *dom*}`. As you see, this search string matches `{\tt domain}`, `{\tt domain constructor}`, `{\tt subdomain}`, and so on.

```
\beginmenu
  \menudownlink{{3.6.1. Logical Searches}}{ugLogicalSearchesPage}
\endmenu
\endscroll
\autobuttons
\end{page}
```

8.0.63 Logical Searches

<ug03.ht>+≡

```
\begin{page}{ugLogicalSearchesPage}{3.6.1. Logical Searches}
\beginscroll
```

For more complicated searches, you can use `\spadSyntax{and}`, `\spadSyntax{or}`, and `\spadSyntax{not}` with basic search strings; write logical expressions using these three operators just as in the Axiom language. For example, `{\tt domain or package}` matches the two entries `{\tt domain}` and `{\tt package}`. Similarly, `{\tt dom* and *con*}` matches `{\tt domain constructor}` and others. Also `{\tt not *a*}` matches every entry that does not contain the letter `{\tt a}` somewhere.

Use parentheses for grouping. For example, `{\tt dom* and (not *con*)}` matches `{\tt domain}` but not `{\tt domain constructor}`.

There is no limit to how complex your logical expression can be. For example, `\centerline{{{ {\tt a* or b* or c* or d* or e* and (not *a*) }}}}` is a valid expression.

```
\endscroll
\autobuttons
\end{page}
```

8.0.64 Example Pages

```

<ug03.ht>+≡
\begin{page}{ugHyperExamplePage}{3.7. Example Pages}
\beginscroll
%
Many pages have Axiom example commands.
%
Here are two:
\spadpaste{a:= x**2 + 1 \bound{a}}
\spadpaste{(a - 2)**2 \free{a}}
%
Each command has an active ‘‘button’’ along the left margin.
When you click on this button, the output for the command is
‘‘pasted-in.’’
Click again on the button and you see that the pasted-in output
disappears.

Maybe you would like to run an example?
To do so, just click on any part of its text!
When you do, the example line is copied into a new interactive
Axiom buffer for this Hyperdoc page.

Sometimes one example line cannot be run before you run an earlier one.
Don't worry---Hyperdoc automatically runs all the necessary
lines in the right order!
For instance, the second example line above refers to \spad{a} which is
assigned in the first example line.
What happens if you first click on the second example line?
Axiom first issues the first line (to assign \spad{a}), then the
second (to do the computation using \spad{a}).

The new interactive Axiom buffer disappears when you leave
Hyperdoc.
If you want to get rid of it beforehand,
use the {\bf Cancel} button of the X Window manager
or issue the Axiom system command \spadsys{close.}

  \beginscroll
```

In this chapter we discuss how to collect Axiom statements and commands into files and then read the contents into the workspace.

We also show how to display the results of your computations in several different styles including `\texht{\TeX}{TeX}`, FORTRAN and monospace two-dimensional format. `\footnote{\texht{\TeX}{TeX}}` is a trademark of the American Mathematical Society.}

The printed version of this book uses the Axiom `\texht{\TeX}{TeX}` output formatter.

When we demonstrate a particular output style, we will need to turn `\texht{\TeX}{TeX}` formatting off and the output style on so that the correct output is shown in the text.

9.0.67 Input Files

⇒ “notitle” (ugLangBlocksPage) 9.0.76 on page 1961

ug04.ht+≡

```
\begin{page}{ugInOutInPage}{4.1. Input Files}
\beginscroll
%
```

In this section we explain what an {\it input file} is and why you would want to know about it.

We discuss where Axiom looks for input files and how you can direct it to look elsewhere.

We also show how to read the contents of an input file into the \spadgloss{workspace} and how to use the \spadgloss{history} facility to generate an input file from the statements you have entered directly into the workspace.

An {\it input} file contains Axiom expressions and system commands.

Anything that you can enter directly to Axiom can be put into an input file.

This is how you save input functions and expressions that you wish to read into Axiom more than one time.

To read an input file into Axiom, use the \spadcmd{read} system command.

For example, you can read a file in a particular directory by issuing

```
\begin{verbatim}
)read /spad/src/input/matrix.input
\end{verbatim}
```

The “{\bf .input}” is optional; this also works:

```
\begin{verbatim}
)read /spad/src/input/matrix
\end{verbatim}
```

What happens if you just enter

```
\spadcmd{read matrix.input} or even \spadcmd{read matrix}?
```

Axiom looks in your current working directory for input files that are not qualified by a directory name.

Typically, this directory is the directory from which you invoked Axiom.

To change the current working directory, use the \spadcmd{cd} system command. The command \spadsys{cd} by itself shows the current working directory.

To change it to

the \spadsys{src/input} subdirectory for user ‘‘babar’’,
issue

```
\begin{verbatim}
)cd /u/babar/src/input
\end{verbatim}
```

Axiom looks first in this directory for an input file.

If it is not found, it looks in the system’s directories, assuming you meant some input file that was provided with Axiom.

```
\beginImportant
```

If you have the Axiom history facility turned on (which it is by default), you can save all the lines you have entered into the workspace by entering

```
\begin{verbatim}
)history )write
\end{verbatim}
```

Axiom tells you what input file to edit to see your statements.

The file is in your home directory or in the directory you specified with \spadsys{)cd}.

```
\endImportant
```

In \downlink{‘‘Blocks’’}{ugLangBlocksPage} in Section 5.2

```
\ignore{ugLangBlocks}
```

we discuss using indentation in input files to group statements into {\it blocks.}

```
\endscroll
```

```
\autobuttons
```

```
\end{page}
```

9.0.68 The .axiom.input File

```
<ug04.ht>+≡
\begin{page}{ugInOutSpadprofPage}{4.2. The .axiom.input File}
\beginscroll
```

When Axiom starts up, it tries to read the input file
{\bf .axiom.input} from your home
directory.

If there is no {\bf axiom.input} in your home directory, it reads the copy
located in its own {\bf src/input} directory.

The file usually contains
system commands to personalize your Axiom environment.
In the remainder of this section we mention a few things
that users frequently place in their
{\bf axiom.input} files.

In order to have FORTRAN output always produced from your
computations, place the system command
\spadcmd{set output fortran on}
in {\bf axiom.input}.

If you do not want to be prompted for confirmation when you issue
the \spadcmd{quit} system command, place
\spadcmd{set quit unprotected}
in {\bf axiom.input}.

If you then decide that you do want to be prompted, issue
\spadcmd{set quit protected}.

This is the default setting
so that new users do not leave Axiom
inadvertently.\footnote{The
system command \spadsys{pquit} always prompts you for
confirmation.}

To see the other system variables you can set, issue \spadsys{set}
or use the Hyperdoc {\bf Settings} facility to view and change
Axiom system variables.

```
\endscroll
\autobuttons
\end{page}
```

9.0.69 Common Features of Using Output Formats

```

<ug04.ht>+≡
\begin{page}{ugInOutPage}{4.3. Common Features of Using Output Formats}
\beginscroll

```

In this section we discuss how to start and stop the display of the different output formats and how to send the output to the screen or to a file.

To fix ideas, we use FORTRAN output format for most of the examples.

You can use the `\spadcmd{set output}` system command to toggle or redirect the different kinds of output. The name of the kind of output follows ‘‘output’’ in the command. The names are

```

\indent{0}
\beginitems
\item[fortran] for FORTRAN output.
\item[algebra] for monospace two-dimensional mathematical output.
\item[tex]     for \texht{\TeX}{TeX} output.
\item[html]    for HTML output.
\item[mathml]  for MathML output.
\item[script]  for IBM Script Formula Format output.
\enditems
\indent{0}

```

For example, issue `\spadsys{set output fortran on}` to turn on FORTRAN format and issue `\spadsys{set output fortran off}` to turn it off. By default, `{\tt algebra}` is `{\tt on}` and all others are `{\tt off}`. When output is started, it is sent to the screen.

To send the output to a file, give the file name without directory or extension.

Axiom appends a file extension depending on the kind of output being produced.

```

\xtc{
Issue this to redirect FORTRAN output to, for example, the file
{\bf linalg.sfort}.
}{
\spadpaste{set output fortran linalg}
}
\noOutputXtc{

```

You must {\it also} turn on the creation of FORTRAN output.
The above just says where it goes if it is created.

```
{
\spadpaste{)set output fortran on}
}
```

In what directory is this output placed?

It goes into the directory from which you started Axiom,
or if you have used the \spadsys{)cd} system command, the one
that you specified with \spadsys{)cd}.

You should use \spadcmd{)cd} before you send the output to the file.

```
\noOutputXtc{
```

You can always direct output back to the screen by issuing this.

```
{
\spadpaste{)set output fortran console}
}
```

```
\noOutputXtc{
```

Let's make sure FORTRAN formatting is off so that nothing we
do from now on produces FORTRAN output.

```
{
\spadpaste{)set output fortran off}
}
```

```
\noOutputXtc{
```

We also delete the demonstrated output file we created.

```
{
\spadpaste{)system rm linalg.sfort}
}
```

You can abbreviate the words ‘‘\spad{on},’’ ‘‘\spad{off},’’ and
‘‘\spad{console},’’ to the minimal number
of characters needed to distinguish them.
Because of this, you cannot send output to files called
{\bf on.sfort, off.sfort, of.sfort,
console.sfort, consol.sfort} and so on.

The width of the output on the page is set by

```
\spadcmd{)set output length}
```

for all formats except FORTRAN.

Use \spadcmd{)set fortran fortlength} to

change the FORTRAN line length from its default value of \spad{72}.

\free{algon texoff}}
}
\noOutputXtc{
Issue this to turn off this kind of formatting.
}{
\spadpaste{)set output algebra off}
}
\noOutputXtc{
Turn \texht{\TeX}{\TeX}{ } output on again.
}{
\spadpaste{)set output tex on}
}
```

The characters used for the matrix brackets above are rather ugly.
You get this character set when you issue
`\spadcmd{)set output characters plain}`.

This character set should be used when you are running on a machine that does not support the IBM extended ASCII character set. If you are running on an IBM workstation, for example, issue `\spadcmd{}set output characters default}` to get better looking output.

9.0.71 TeX Format

<ug04.ht>+≡

```
\begin{page}{ugInOutTeXPage}{4.5. TeX Format}
\beginscroll
```

Axiom can produce `\texht{\TeX}{\TeX}{}` output for your expressions.

The output is produced using macros from the `\texht{\LaTeX}{\LaTeX}` document preparation system by Leslie Lamport. `\footnote{See Leslie Lamport, {\it LaTeX: A Document Preparation System,} Reading, Massachusetts: Addison-Wesley Publishing Company, Inc., 1986.}`

The printed version of this book was produced using this formatter.

```
\noOutputXtc{
```

To turn on `\texht{\TeX}{\TeX}{}` output formatting, issue this.

```
}{
\spadpaste{)set output tex on \bound{texon}}
}
```

Here is an example of its output.

```
\begin{verbatim}
```

```
matrix [[i***i + j*%i*y**j for i in 1..2] for j in 3..4]
```

```
\[
```

```
\left[
```

```
\begin{array}{cc}
```

```
\displaystyle {{3 \ \%i \ {y \sp 3}}+x}&
```

```
\displaystyle {{3 \ \%i \ {y \sp 3}}+{2 \ {x \sp 2}}}\ \
```

```
\displaystyle {{4 \ \%i \ {y \sp 4}}+x}&
```

```
\displaystyle {{4 \ \%i \ {y \sp 4}}+{2 \ {x \sp 2}}}
```

```
\end{array}
```

```
\right]
```

```
\leqno(3)
```

```
\]
```

```
%Axiom STEP NUMBER: 3
```

```
\end{verbatim}
```

To turn `\texht{\TeX}{\TeX}{}` output formatting off, issue `\spadsys{)set output tex off}`.

The `\texht{\LaTeX}{\LaTeX}` macros in the output generated by Axiom are all standard except for the following definitions:

```
\begin{verbatim}
```

```
\def\csch{\mathop{\rm csch}\nolimits}
```

```
\def\erf{\mathop{\rm erf}\nolimits}
```

```

\def\zag#1#2{

9.0.73 FORTRAN Format

```

<ug04.ht>+≡
\begin{page}{ugInOutFortranPage}{4.7. FORTRAN Format}
\beginscroll

```

In addition to turning FORTRAN output on and off and stating where the output should be placed, there are many options that control the appearance of the generated code. In this section we describe some of the basic options. Issue `\spadcmd{set fortran}` to see a full list with their current settings.

The output FORTRAN expression usually begins in column 7. If the expression needs more than one line, the ampersand character `\spadSyntax{\&}` is used in column 6. Since some versions of FORTRAN have restrictions on the number of lines per statement, Axiom breaks long expressions into segments with a maximum of 1320 characters (20 lines of 66 characters) per segment. If you want to change this, say, to 660 characters, issue the system command `\spadcmd{set fortran explength 660}`. You can turn off the line breaking by issuing `\spadcmd{set fortran segment off}`. Various code optimization levels are available. `% \noOutputXtc{ FORTRAN output is produced after you issue this. }{ \spadpaste{set output fortran on \bound{forton}} }` `\noOutputXtc{ For the initial examples, we set the optimization level to 0, which is the lowest level. }{ \spadpaste{set fortran optlevel 0 \bound{opt0}\free{forton}} }` `\noOutputXtc{ The output is usually in columns 7 through 72, although fewer columns are used in the following examples so that the output fits nicely on the page. }{ \spadpaste{set fortran fortlength 60} }` `\xtc{ By default, the output goes to the screen and is displayed before the standard Axiom two-dimensional output. In this example, an assignment to the variable \spad{R1} was generated because this is the result of step 1. }{ \spadpaste{(x+y)**3 \free{opt0}} }`

`\xtc{ Here is an example that illustrates the line breaking. }`
`{ \spadpaste{(x+y+z)**3 \free{opt0}} }`
`}`

Note in the above examples that integers are generally converted to floating point numbers, except in exponents.

This is the default behavior but can be turned off by issuing `\spadcmd{set fortran ints2floats off}`.

The rules governing when the conversion is done are:

```
\indent{4}
```

```
\beginitems
```

```
\item[1. ] If an integer is an exponent, convert it to a floating point
```

number if it is greater than 32767 in absolute value, otherwise leave it as an integer.

\item[2.] Convert all other integers in an expression to floating point numbers.

\enditems

\indent{0}

These rules only govern integers in expressions.

Numbers generated by Axiom for \spad{DIMENSION} statements are also integers.

To set the type of generated FORTRAN data, use one of the following:

\begin{verbatim}

)set fortran defaulttype REAL

)set fortran defaulttype INTEGER

)set fortran defaulttype COMPLEX

)set fortran defaulttype LOGICAL

)set fortran defaulttype CHARACTER

\end{verbatim}

\xctc{

When temporaries are created, they are given a default type of {\tt REAL.}

Also, the {\tt REAL} versions of functions are used by default.

{

\spadpaste{sin(x) \free{opt1}}

}

\noOutputXtc{

At optimization level 1, Axiom removes common subexpressions.

{

\spadpaste{)set fortran optlevel 1 \bound{opt1}\free{forton}}

}

\xctc{

{

\spadpaste{(x+y+z)**3 \free{opt1}}

}

\noOutputXtc{

This changes the precision to {\tt DOUBLE}.

Substitute \spad{single} for \spad{double}

to return to single precision.

{

\spadpaste{)set fortran precision double \free{opt1}\bound{double1}}

}

\xctc{

Complex constants display the precision.

{

```

\spadpaste{2.3 + 5.6*%i \free{double1}}
}
\xtc{
The function names that Axiom generates depend on the chosen
precision.
}{
\spadpaste{sin %e \free{double1}}
}
\noOutputXtc{
Reset the precision to \spad{single} and look at these two
examples again.
}{
\spadpaste{)set fortran precision single \free{opt1}\bound{single1}}
}
\xtc{
}{
\spadpaste{2.3 + 5.6*%i \free{single1}}
}
\xtc{
}{
\spadpaste{sin %e \free{single1}}
}
\xtc{
Expressions that look like lists, streams, sets or matrices cause
array code to be generated.
}{
\spadpaste{[x+1,y+1,z+1] \free{opt1}}
}
\xtc{
A temporary variable is generated to be the name of the array.
This may have to be changed in your particular application.
}{
\spadpaste{set[2,3,4,3,5] \free{opt1}}
}
\xtc{
By default, the starting index for generated FORTRAN arrays is \spad{0}.
}{
\spadpaste{matrix [[2.3,9.7],[0.0,18.778]] \free{opt1}}
}
\noOutputXtc{
To change the starting index for generated FORTRAN arrays to be \spad{1},
issue this.
This value can only be \spad{0} or \spad{1}.
}{
\spadpaste{)set fortran startindex 1 \free{opt1}\bound{start1}}
}

```

```

\xtc{
Look at the code generated for the matrix again.
}{

\begin{page}{ugLangPage}{5. Introduction to the Axiom Interactive Language}
\beginscroll

```

In this chapter we look at some of the basic components of the Axiom language that you can use interactively. We show how to create a `\spadgloss{block}` of expressions, how to form loops and list iterations, how to modify the sequential evaluation of a block and how to use `\tt if-then-else` to evaluate parts of your program conditionally. We suggest you first read the boxed material in each section and then proceed to a more thorough reading of the chapter.

9.0.75 Immediate and Delayed Assignments

⇒ “notitle” (ugUserDelayPage) 10.0.103 on page 2077

<ug05.ht>+≡

```
\begin{page}{ugLangAssignPage}{5.1. Immediate and Delayed Assignments}
\beginscroll
```

A `\spadgloss{variable}` in Axiom refers to a value.

A variable has a name beginning with an uppercase or lowercase alphabetic character, `\axiomSyntax{\%}`, or `\axiomSyntax{!}`.

Successive characters (if any) can be any of the above, digits, or `\axiomSyntax{?}`.

Case is distinguished.

The following are all examples of valid, distinct variable names:

```
\begin{verbatim}
a          tooBig?      a1B2c3%!?
A          %j           numberOfPoints
beta6      %J           numberofpoints
\end{verbatim}
```

The `\axiomSyntax{:=}` operator is the immediate `\spadgloss{assignment}` operator.

Use it to associate a value with a variable.

`\beginImportant`

The syntax for immediate assignment for a single variable is

```
\centerline{{{ \it variable} \axiom{:=} { \it expression} }}
```

The value returned by an immediate assignment is the value of `{ \it expression}`.

`\endImportant`

`\xtc{`

The right-hand side of the expression is evaluated, yielding `\axiom{1}`. This value is then assigned to `\axiom{a}`.

```
}{
\spadpaste{a := 1 \bound{a}}
}
```

`\xtc{`

The right-hand side of the expression is evaluated, yielding `\axiom{1}`. This value is then assigned to `\axiom{b}`.

Thus `\axiom{a}` and `\axiom{b}` both have the value `\axiom{1}` after the sequence of assignments.

```
}{
\spadpaste{b := a \free{a}\bound{b}}
```

```

}
\xtc{
What is the value of \axiom{b} if \axiom{a} is
assigned the value \axiom{2}?
}{
\spadpaste{a := 2 \bound{a2}}
}
\xtc{
As you see, the value of \axiom{b} is left unchanged.
}{
\spadpaste{b \free{b}}
}
This is what we mean when we say this kind of assignment is
{\it immediate};
\axiom{b} has no dependency on \axiom{a} after the initial assignment.
This is the usual notion of assignment found in programming
languages such as C,
PASCAL
and FORTRAN.

```

Axiom provides delayed assignment with `\axiomSyntax{==}`.
This implements a
delayed evaluation of the right-hand side and dependency
checking.

```

\beginImportant
The syntax for delayed assignment is
\centerline{{{\it variable} \axiom{==} {\it expression}}}}
The value returned by a delayed assignment is \void{}.
\endImportant

```

```

\xtc{
Using \axiom{a} and \axiom{b} as above, these are the corresponding
delayed assignments.
}{
\spadpaste{a == 1 \bound{ad}}
}
\xtc{
}{
\spadpaste{b == a \free{ad}\bound{bd}}
}
\xtc{
The right-hand side of each delayed assignment
is left unevaluated until the
variables on the left-hand sides are evaluated.
Therefore this evaluation and \ldots

```

```

}{
\spadpaste{a \free{ad}}
}
\xtc{
this evaluation seem the same as before.
}{
\spadpaste{b \free{bd}}
}
\xtc{
If we change \axiom{a} to \axiom{2}
}{
\spadpaste{a == 2 \bound{ad2}}
}
\xtc{
then
\axiom{a} evaluates to \axiom{2}, as expected, but
}{
\spadpaste{a \free{ad2}}
}
\xtc{
the value of \axiom{b} reflects the change to \axiom{a}.
}{
\spadpaste{b \free{bd ad2}}
}

```

It is possible to set several variables at the same time by using a `\spadgloss{tuple}` of variables and a tuple of expressions.^{\footnote{A `\spadgloss{tuple}` is a collection of things separated by commas, often surrounded by parentheses.}}

```

\beginImportant
The syntax for multiple immediate assignments is
\centerline{{{ \tt ( \subscriptIt{var}{1}, \subscriptIt{var}{2},
\ldots, \subscriptIt{var}{N} ) := ( \subscriptIt{expr}{1},
\subscriptIt{expr}{2}, \ldots, \subscriptIt{expr}{N} ) }}}
The value returned by an immediate assignment is the value of
\subscriptIt{expr}{N}.
\endImportant

```

```

\xtc{
This sets \axiom{x} to \axiom{1} and \axiom{y} to \axiom{2}.
}{
\spadpaste{(x,y) := (1,2) \bound{x}\bound{y}}
}
Multiple immediate assignments are parallel in the sense that the

```

expressions on the right are all evaluated before any assignments on the left are made.

However, the order of evaluation of these expressions is undefined.

`\xtc{`

You can use multiple immediate assignment to swap the values held by variables.

`}{`

`\spadpaste{(x,y) := (y,x) \free{x y}\bound{swap}}`

`}`

`\xtc{`

`\axiom{x}` has the previous value of `\axiom{y}`.

`}{`

`\spadpaste{x \free{swap}}`

`}`

`\xtc{`

`\axiom{y}` has the previous value of `\axiom{x}`.

`}{`

`\spadpaste{y \free{swap}}`

`}`

There is no syntactic form for multiple delayed assignments.

See the discussion in

`\downlink{'Delayed Assignments vs. Functions with No Arguments'}`

`{ugUserDelayPage}`

in Section 6.8\ignore{ugUserDelay}

about how Axiom differentiates between delayed assignments and user functions of no arguments.

%%
```

A `\spadgloss{block}` is a sequence of expressions evaluated in the order that they appear, except as modified by control expressions such as `\axiom{break}`,

```
\spadkey{break}
\axiom{return},
\spadkey{return}
\axiom{iterate} and
\spadkey{iterate}
\axiom{if-then-else} constructions.
```

The value of a block is the value of the expression last evaluated in the block.

To leave a block early, use `\axiomSyntax{=>}`.

For example, `\axiom{i < 0 => x}`.

The expression before the `\axiomSyntax{=>}` must evaluate to

`\axiom{true}` or `\axiom{false}`.

The expression following the `\axiomSyntax{=>}` is the return value for the block.

A block can be constructed in two ways:

```
\indent{4}
\beginitems
\item[1. ] the expressions can be separated by semicolons
and the resulting expression surrounded by parentheses, and
\item[2. ] the expressions can be written on succeeding lines with
each line indented the same number of spaces (which must be greater
than zero).
```

A block entered in this form is called a `\spadgloss{pile}`.

```
\enditems
\indent{0}
```

Only the first form is available if you are entering expressions directly to Axiom.

Both forms are available in `{\bf .input}` files.

`\beginImportant`

The syntax for a simple block of expressions entered interactively is
`\centerline{{\tt (\subscriptIt{expression}{1};`
`\subscriptIt{expression}{2}; \ldots; \subscriptIt{expression}{N})}}`
 The value returned by a block is the value of an
`\axiomSyntax{=>} expression`, or `\subscriptIt{expression}{N}`
 if no `\axiomSyntax{=>}` is encountered.

`\endImportant`

In `{\bf .input}` files, blocks can also be written using

`\spadglossSee{piles}{pile}`.

The examples throughout this book are assumed to come from
`{\bf .input}` files.

`\xtc{`

In this example, we assign a rational number to `\axiom{a}` using a block consisting of three expressions.

This block is written as a pile.

Each expression in the pile has the same indentation, in this case two spaces to the right of the first line.

`}{`

`\begin{spadsrc}`

`a :=`

`i := gcd(234,672)`

`i := 3*i**5 - i + 1`

`1 / i`

`\end{spadsrc}`

`}`

`\xtc{`

Here is the same block written on one line.

This is how you are required to enter it at the input prompt.

`}{`

`\spadpaste{a := (i := gcd(234,672); i := 3*i**5 - i + 1; 1 / i)}`

`}`

`\xtc{`

Blocks can be used to put several expressions on one line.

The value returned is that of the last expression.

`}{`

`\spadpaste{(a := 1; b := 2; c := 3; [a,b,c]) \bound{a b c}}`

`}`

Axiom gives you two ways of writing a block and the preferred way in an `{\bf .input}` file is to use a pile. Roughly speaking, a pile is

a block whose constituent expressions are indented the same amount. You begin a pile by starting a new line for the first expression, indenting it to the right of the previous line. You then enter the second expression on a new line, vertically aligning it with the first line. And so on. If you need to enter an inner pile, further indent its lines to the right of the outer pile. Axiom knows where a pile ends. It ends when a subsequent line is indented to the left of the pile or the end of the file.

```
\xrc{
Blocks can be used to perform several steps before an assignment
(immediate or delayed) is made.
}{
\begin{spadsrc}[\free{a b}]
d :=
    c := a**2 + b**2
    sqrt(c * 1.3)
\end{spadsrc}
}
\xrc{
Blocks can be used in the arguments to functions.
(Here \axiom{h} is assigned \axiom{2.1 + 3.5}.)
}{
\begin{spadsrc}[\bound{h}]
h := 2.1 +
    1.0
    3.5
\end{spadsrc}
}
\xrc{
Here the second argument to \axiomFun{eval} is \axiom{x = z}, where
the value of \axiom{z} is computed in the first line of the block
starting on the second line.
}{
\begin{spadsrc}
eval(x**2 - x*y**2,
    z := %pi/2.0 - exp(4.1)
    x = z
)
\end{spadsrc}
}
\xrc{
Blocks can be used in the clauses of \axiom{if-then-else}
expressions (see \downlink{'if-then-else'}{ugLangIfPage})
}
```

```

in Section 5.3\ignore{ugLangIf}).
}{
\spadpaste{if h > 3.1 then 1.0 else (z := cos(h); max(z,0.5)) \free{h}}
}
\xtc{
This is the pile version of the last block.
}{
\begin{spadsrc}[\free{h}]
if h > 3.1 then
    1.0
else
    z := cos(h)
    max(z,0.5)
\end{spadsrc}
}
\xtc{
Blocks can be nested.
}{
\spadpaste{
a := (b := factorial(12); c := (d := eulerPhi(22); factorial(d));b+c)}
}
\xtc{
This is the pile version of the last block.
}{
\begin{spadsrc}
a :=
    b := factorial(12)
    c :=
        d := eulerPhi(22)
        factorial(d)
    b+c
\end{spadsrc}
}

\xtc{
Since \axiom{c + d} does equal \axiom{3628855}, \axiom{a} has the value
of \axiom{c} and the last line is never evaluated.
}{
\begin{spadsrc}
a :=
    c := factorial 10
    d := fibonacci 10
    c + d = 3628855 => c
    d
\end{spadsrc}
}

```

9.0.77 if-then-else

⇒ “notitle” (ugTypesResolvePage) 7.0.53 on page 1892

⇒ “notitle” (ugTypesPkgCallPage) 7.0.52 on page 1882

```
<ug05.ht>+≡
\begin{page}{ugLangIfPage}{5.3. if-then-else}
\beginscroll
```

Like many other programming languages, Axiom uses the three keywords `\spadkey{if}` `\axiom{if, then}` `\spadkey{then}` and `\axiom{else}` `\spadkey{else}` to form conditional expressions.

The `\axiom{else}` part of the conditional is optional.

The expression between the `\axiom{if}` and `\axiom{then}` keywords is a

`\spadgloss{predicate}`: an expression that evaluates to or is convertible to either `{\tt true}` or `{\tt false}`, that is, a `\axiomType{Boolean}`.

```
\beginImportant The syntax for conditional expressions is
\centerline{{{ \tt if {\it predicate} then \subscriptIt{expression}{1}
else \subscriptIt{expression}{2} }}} where the \axiom{else}
\subscriptIt{\it expression}{2} part is optional. The value returned
from a conditional expression is \subscriptIt{\it expression}{1} if
the predicate evaluates to \axiom{true} and \subscriptIt{\it
expression}{2} otherwise. If no \axiom{else} clause is given, the
value is always \void{}. \endImportant
```

An `\axiom{if-then-else}` expression always returns a value.

If the

`\axiom{else}` clause is missing then the entire expression returns `\void{}`.

If both clauses are present, the type of the value returned by `\axiom{if}` is obtained by resolving the types of the values of the two clauses.

See `\downlink{‘Resolving Types’}{ugTypesResolvePage}`

in Section 2.10\ignore{ugTypesResolve}

for more information.

The predicate must evaluate to, or be convertible to, an object of type `\axiomType{Boolean}`: `{\tt true}` or `{\tt false}`.

By default, the equal sign `\spadopFrom{=}{Equation}` creates an equation.

```
\xctc{
```

This is an equation.

In particular, it is an object of type
`\axiomType{Equation Polynomial Integer}.`

```
{
\spadpaste{x + 1 = y}
}
```

However, for predicates in `\axiom{if}` expressions, Axiom places a default target type of `\axiomType{Boolean}` on the predicate and equality testing is performed.

Thus you need not qualify the `\axiomSyntax{=}` in any way.

In other contexts you may need to tell Axiom that you want to test for equality rather than create an equation.

In those cases, use `\axiomSyntax{@}` and a target type of `\axiomType{Boolean}`.

See `\downlink{'Package Calling and Target Types'}`
`{ugTypesPkgCallPage}` in Section 2.9
`\ignore{ugTypesPkgCall}` for more information.

The compound symbol meaning ‘‘not equal’’ in Axiom is
`‘\texht{$\sim =}$\axiom{~}=’.`

This can be used directly without a package call or a target specification. The expression

`\axiom{a} \texht{$\sim =}$\axiom{~}= \axiom{b}` is directly translated into `\axiom{not (a = b)}`.

Many other functions have return values of type `\axiomType{Boolean}`.

These include `\axiom{<}`, `\axiom{<=}`, `\axiom{>}`,
`\axiom{>=}`, `\texht{$\sim =}$\axiom{~}=` and `\axiom{member?}`.

By convention, operations with names ending in `\axiomSyntax{?}` return `\axiomType{Boolean}` values.

The usual rules for piles are suspended for conditional expressions.

In `{\bf .input}` files, the `\axiom{then}` and `\axiom{else}` keywords can begin in the same column as the corresponding `\axiom{if}` but may also appear to the right.

Each of the following styles of writing `\axiom{if-then-else}` expressions is acceptable:

```
\begin{verbatim}
if i>0 then output("positive") else output("nonpositive")
```

```
if i > 0 then output("positive")
  else output("nonpositive")
```

```
if i > 0 then output("positive")
else output("nonpositive")
```

```
if i > 0
```

```

then output("positive")
else output("nonpositive")

if i > 0
  then output("positive")
  else output("nonpositive")
\end{verbatim}

```

A block can follow the `\axiom{then}` or `\axiom{else}` keywords. In the following two assignments to `\axiom{a}`, the `\axiom{then}` and `\axiom{else}` clauses each are followed by two-line piles. The value returned in each is the value of the second line.

```

\begin{verbatim}
a :=
  if i > 0 then
    j := sin(i * pi())
    exp(j + 1/j)
  else
    j := cos(i * 0.5 * pi())
    log(abs(j)**5 + 1)

a :=
  if i > 0
  then
    j := sin(i * pi())
    exp(j + 1/j)
  else
    j := cos(i * 0.5 * pi())
    log(abs(j)**5 + 1)
\end{verbatim}

```

These are both equivalent to the following:

```

\begin{verbatim}
a :=
  if i > 0 then (j := sin(i * pi()); exp(j + 1/j))
  else (j := cos(i * 0.5 * pi()); log(abs(j)**5 + 1))
\end{verbatim}

```
\begin{page}{ugLangLoopsPage}{5.4. Loops}
\beginscroll
```

A `\spadgloss{loop}` is an expression that contains another expression, called the `{\it loop body}`, which is to be evaluated zero or more times.

All loops contain the `\axiom{repeat}` keyword and return `\void{}`. Loops can contain inner loops to any depth.

```
\beginImportant
```

The most basic loop is of the form

```
\centerline{{\axiom{repeat} {\it loopBody}}}
```

Unless `{\it loopBody}` contains a `\axiom{break}` or `\axiom{return}` expression, the loop repeats forever.

The value returned by the loop is `\void{}`.

```

Axiom tries to determine completely the type of every object in a loop and then to translate the loop body to LISP or even to machine code.

This translation is called `\spadglossSee{compilation}{compiler}`.

If Axiom decides that it cannot compile the loop, it issues a message stating the problem and then the following message:

```

%
\centerline{
{{\bf We will attempt to step through and interpret the code.}}}
%
It is still possible that Axiom can evaluate the loop but in
\spadgloss{interpret-code mode}.
See \downlink{'Compiling vs. Interpreting'}{ugUserCompIntPage}
in Section 6.10\ignore{ugUserCompInt} where
this is discussed in terms
of compiling versus interpreting functions.

```

9.0.80 return in Loops

⇒ “notitle” (ugUserBlocksPage) 10.0.113 on page 2130

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsReturnPage}{5.4.2. return in Loops}
\beginscroll
```

A `\axiom{return}` expression is used to exit a function with a particular value.

In particular, if a `\axiom{return}` is in a loop within the `\spadkey{return}` function, the loop is terminated whenever the `\axiom{return}` is evaluated.

```
%> This is a bug! The compiler should never accept allow
%> Void to be the return type of a function when it has to use
%> resolve to determine it.
```

```
\xrc{
Suppose we start with this.
}{
\begin{spadsrc}[\bound{f}]
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
    i := i + 1
\end{spadsrc}
}
```

```
\xrc{
When \axiom{factorial(i)} is big enough, control passes from
inside the loop all the way outside the function, returning the
value of \axiom{i} (or so we think).
```

```
}{
\spadpaste{f() \free{f}}
}
```

What went wrong?

Isn't it obvious that this function should return an integer?

Well, Axiom makes no attempt to analyze the structure of a loop to determine if it always returns a value because, in general, this is impossible.

So Axiom has this simple rule: the type of the function is determined by the type of its body, in this case a block.

The normal value of a block is the value of its last expression, in this case, a loop.

And the value of every loop is `\void{}`!
 So the return type of `\userfun{f}` is `\axiomType{Void}`.

There are two ways to fix this.

The best way is for you to tell Axiom what the return type of `\axiom{f}` is.

You do this by giving `\axiom{f}` a declaration `\axiom{f: () -> Integer}` prior to calling for its value.

This tells Axiom: “trust me---an integer is returned.”

We’ll explain more about this in the next chapter.

Another clumsy way is to add a dummy expression as follows.

```
\xctc{
Since we want an integer, let's stick in a dummy final expression that is
an integer and will never be evaluated.
}{
\begin{spadsrc}[\bound{f1}]
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
    i := i + 1
  0
\end{spadsrc}
}
\xctc{
When we try \userfun{f} again we get what we wanted.
See
\downlink{‘‘Functions Defined with Blocks’’}{ugUserBlocksPage}
in Section 6.15\ignore{ugUserBlocks}
for more information.

9.0.81 break in Loops

⇒ “notitle” (ugLangLoopsReturnPage) 9.0.80 on page 1978

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsBreakPage}{5.4.3. break in Loops}
\beginscroll
```

The `\axiom{break}` keyword is often more useful
`\spadkey{break}`
 in terminating
 a loop.
`%>` and more in keeping with the ideas of structured programming.
 A `\axiom{break}` causes control to transfer to the expression
 immediately following the loop.
 As loops always return `\void{}`,
 you cannot return a value with `\axiom{break}`.
 That is, `\axiom{break}` takes no argument.

`\xctc{`

This example is a modification of the last example in
`\texht{the previous section}{`
`\downlink{'return in Loops'}{ugLangLoopsReturnPage}`
 in Section 5.4.2`\ignore{ugLangLoopsReturn}}.`
 Instead of using `\axiom{return}`, we'll use `\axiom{break}`.
`{`

`\begin{spadsrc}[\bound{f1}]`

`f() ==`

`i := 1`

`repeat`

`if factorial(i) > 1000 then break`

`i := i + 1`

`i`

`\end{spadsrc}`

`}`

`\xctc{`

The loop terminates when `\axiom{factorial(i)}` gets big enough,
 the last line of the function evaluates to the corresponding “good”
 value of `\axiom{i}`, and the function terminates, returning that value.

`{`

`\spadpaste{f() \free{f1}}`

`}`

`\xctc{`

You can only use `\axiom{break}` to terminate the evaluation of one loop.
 Let's consider a loop within a loop, that is, a loop with a nested loop.

First, we initialize two counter variables.

```
{
\spadpaste{(i,j) := (1, 1) \bound{i}\bound{j}}
}
\xtc{
Nested loops must have multiple \axiom{break}
expressions at the appropriate nesting level.
How would you rewrite this so \axiom{(i + j) > 10} is only evaluated once?
}{
\begin{spadsrc}[\free{i j}]
repeat
  repeat
    if (i + j) > 10 then break
    j := j + 1
    if (i + j) > 10 then break
    i := i + 1
\end{spadsrc}
}

\endscroll
\autobuttons
\end{page}
```

```

9.0.82 break vs. => in Loop Bodies

```

<ug05.ht>+≡
\begin{page}{ugLangLoopsBreakVsPage}
{5.4.4. break vs. {\tt =>} in Loop Bodies}
\beginscroll

```

Compare the following two loops:

| | |
|--|--|
| <pre> \begin{verbatim} i := 1 repeat i := i + 1 i > 3 => i output(i) \end{verbatim} </pre> | <pre> i := 1 repeat i := i + 1 if i > 3 then break output(i) </pre> |
|--|--|

In the example on the left, the values $\mathsf{0rSpad}\{2\}$ and $\mathsf{0rSpad}\{3\}$ for $\mathsf{axiom}\{i\}$ are displayed but then the $\mathsf{axiomSyntax}\{=>\}$ does not allow control to reach the call to $\mathsf{axiomFunFrom}\{\mathsf{output}\}\{\mathsf{OutputForm}\}$ again. The loop will not terminate until you run out of space or interrupt the execution. The variable $\mathsf{axiom}\{i\}$ will continue to be incremented because the $\mathsf{axiomSyntax}\{=>\}$ only means to leave the $\{\mathsf{it block},\}$ not the loop.

In the example on the right, upon reaching $\mathsf{0rSpad}\{4\}$, the $\mathsf{axiom}\{\mathsf{break}\}$ will be executed, and both the block and the loop will terminate. This is one of the reasons why both $\mathsf{axiomSyntax}\{=>\}$ and $\mathsf{axiom}\{\mathsf{break}\}$ are provided. Using a $\mathsf{axiom}\{\mathsf{while}\}$ clause (see below) with the $\mathsf{axiomSyntax}\{=>\}$ $\mathsf{spadkey}\{\mathsf{while}\}$ lets you simulate the action of $\mathsf{axiom}\{\mathsf{break}\}$.

```

9.0.83 More Examples of break

⇒ “notitle” (ugLangLoopsForInPage) 9.0.86 on page 2006

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsBreakMorePage}{5.4.5. More Examples of break}
\beginscroll
```

Here we give four examples of `\axiom{repeat}` loops that terminate when a value exceeds a given bound.

```
\texht{\vskip 1pc}{
\xtc{
First, initialize \axiom{i} as the loop counter.
}{
\spadpaste{i := 0 \bound{i}}
}
\xtc{
Here is the first loop.
When the square of \axiom{i} exceeds \axiom{100}, the loop terminates.
}{
\begin{spadsrc}[\free{i}\bound{i1}]
repeat
  i := i + 1
  if i**2 > 100 then break
\end{spadsrc}
}
\xtc{
Upon completion, \axiom{i} should have the value \axiom{11}.
}{
\spadpaste{i \free{i1}}
}
%
%
\xtc{
Do the same thing except use \axiomSyntax{=>} instead
an \axiom{if-then} expression.
}{
\spadpaste{i := 0 \bound{i2}}
}
\xtc{
}{
\begin{spadsrc}[\free{i2}\bound{i3}]
repeat
  i := i + 1
```

```

        i**2 > 100 => break
\end{spadsrc}
}
\xtc{
}{
\spadpaste{i \free{i3}}
}
%
%
\xtc{
As a third example, we use a simple loop to compute \axiom{n!}.
}{
\spadpaste{(n, i, f) := (100, 1, 1) \bound{n}\bound{i4}\bound{f}}
}
\xtc{
Use \axiom{i} as the iteration variable and \axiom{f}
to compute the factorial.
}{
\begin{spadsrc}[\bound{f1}\bound{i5}\free{f i4 n}]
repeat
    if i > n then break
    f := f * i
    i := i + 1
\end{spadsrc}
}
\xtc{
Look at the value of \axiom{f}.
}{
\spadpaste{f \free{f1}}
}
%
%
\xtc{
Finally, we show an example of nested loops.
First define a four by four matrix.
}{
\spadpaste{m :=
matrix [[21,37,53,14], [8,-24,22,-16], [2,10,15,14],
[26,33,55,-13]] \bound{m2}}
}
\xtc{
Next, set row counter \axiom{r} and column counter \axiom{c} to
\mathOrSpad{1}.
Note: if we were writing a function, these would all be local
variables rather than global workspace variables.
}{

```

```

\spadpaste{(r, c) := (1, 1) \bound{r}\bound{c}}
}
\xtc{
Also, let \axiom{lastrow} and
\axiom{lastcol} be the final row and column index.
}{
\spadpaste{(lastrow, lastcol) := (nrows(m), ncols(m))
\bound{lastrow}\bound{lastcol}\free{m2}}
}
%
\xtc{
Scan the rows looking for the first negative element.
We remark that you can reformulate this example in a better, more
concise form by using a \axiom{for} clause with \axiom{repeat}.
See
\downlink{'for Loops'}{ugLangLoopsForInPage}
in Section 5.4.8\ignore{ugLangLoopsForIn}
for more information.
}{
\begin{spadsrc}[\free{m2} r c lastrow lastcol]
repeat
  if r > lastrow then break
  c := 1
  repeat
    if c > lastcol then break
    if elt(m,r,c) < 0 then
      output [r, c, elt(m,r,c)]
      r := lastrow
      break      -- don't look any further
    c := c + 1
  r := r + 1

9.0.85 while Loops

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsWhilePage}{5.4.7. while Loops}
\beginscroll
```

The `\axiom{repeat}` in a loop can be modified by adding one or more `\axiom{while}` clauses.

```
\spadkey{while}
```

Each clause contains a `\spadgloss{predicate}` immediately following the `\axiom{while}` keyword.

The predicate is tested `{\it before}` the evaluation of the body of the loop.

The loop body is evaluated whenever the predicates in a `\axiom{while}` clause are all `\axiom{true}`.

```
\beginImportant
```

The syntax for a simple loop using `\axiom{while}` is

```
\centerline{{\axiom{while} {\it predicate} \axiom{repeat} {\it loopBody}}}
```

The `{\it predicate}` is evaluated before `{\it loopBody}` is evaluated.

A `\axiom{while}` loop terminates immediately when `{\it predicate}` evaluates to `\axiom{false}` or when a `\axiom{break}` or `\axiom{return}` expression is evaluated in `{\it loopBody}`.

The value returned by the loop is `\void{}`.

```
\endImportant
```

```
\xctc{
```

Here is a simple example of using `\axiom{while}` in a loop.

We first initialize the counter.

```
}{
\spadpaste{i := 1 \bound{i}}
}
```

```
\xctc{
```

The steps involved in computing this example are

(1) set `\axiom{i}` to `\axiom{1}`, (2) test the condition `\axiom{i < 1}` and determine that it is not true, and (3) do not evaluate the loop body and therefore do not display `\axiom{"hello"}`.

```
}{
\begin{spadsrc}[\free{i}]
```

```
while i < 1 repeat
```

```
  output "hello"
```

```
  i := i + 1
```

```
\end{spadsrc}
```

```
}
```

```
\xctc{
```

If you have multiple predicates to be tested use the

```

logical \axiom{and} operation to separate them.
Axiom evaluates these predicates from left to right.
}{
\spadpaste{(x, y) := (1, 1) \bound{x}\bound{y}}
}
\xtc{
}{
\begin{spadsrc}[\free{x y}]
while x < 4 and y < 10 repeat
    output [x,y]
    x := x + 1
    y := y + 2
\end{spadsrc}
}
\xtc{
A \axiom{break} expression can be included in a loop body to terminate
a loop even if the predicate in any \axiom{while} clauses are not
\axiom{false}.
}{
\spadpaste{(x, y) := (1, 1) \bound{x1}\bound{y1}}
}
\xtc{
This loop has multiple \axiom{while} clauses and the loop terminates
before any one of their conditions evaluates to \axiom{false}.
}{
\begin{spadsrc}[\free{x1 y1}]
while x < 4 while y < 10 repeat
    if x + y > 7 then break
    output [x,y]
    x := x + 1
    y := y + 2
\end{spadsrc}
}
\xtc{
Here's a different version of the nested loops that looked
for the first negative element in a matrix.
}{
\spadpaste{m := matrix [[21,37,53,14], [8,-24,22,-16], [2,10,15,14],
[26,33,55,-13]] \bound{m2}}
}
\xtc{
Initialized the row index to \axiom{1} and
get the number of rows and columns.
If we were writing a function, these would all be
local variables.
}{

```

```

\spadpaste{r := 1 \bound{r}}
}
\xtc{
}{
\spadpaste{(lastrow, lastcol) := (nrows(m), ncols(m))
\bound{lastrow}\bound{lastcol}\free{m2}}
}
%
\xtc{
Scan the rows looking for the first negative element.
}{

9.0.86 for Loops

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsForInPage}{5.4.8. for Loops}
\beginscroll
```

Axiom provides the `\axiom{for}`
`\spadkey{for}`
 and `\axiom{in}`
`\spadkey{in}`
 keywords in `\axiom{repeat}` loops,
 allowing you to iterate across all
 elements of a list, or to have a variable take on integral values
 from a lower bound to an upper bound.
 We shall refer to these modifying clauses of `\axiom{repeat}` loops as
`\axiom{for}` clauses.
 These clauses can be present in addition to `\axiom{while}` clauses.
 As with all other types of `\axiom{repeat}` loops, `\axiom{break}` can
`\spadkey{break}`
 be used to prematurely terminate the evaluation of the loop.

`\beginImportant`

The syntax for a simple loop using `\axiom{for}` is
`\centerline{{\axiom{for} {\it iterator} \axiom{repeat} {\it loopBody}}}`
 The `{\it iterator}` has several forms.
 Each form has an end test which is evaluated
 before `{\it loopBody}` is evaluated.
 A `\axiom{for}` loop terminates immediately when the end test
 succeeds (evaluates to `\axiom{true}`) or when a `\axiom{break}` or
`\axiom{return}` expression is evaluated in `{\it loopBody}`.
 The value returned by the loop is `\void{}`.
`\endImportant`

`\end{page}`

9.0.87 for i in n..m repeat

⇒ “notitle” (SegmentXmpPage) 3.95.1 on page 1355

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsForInNMPage}{5.4.9. for i in n..m repeat}
\beginscroll
```

If `\axiom{for}`
`\spadkey{for}`
 is followed by a variable name, the `\axiom{in}`
`\spadkey{in}`
 keyword and then an integer segment of the form `\axiom{n..m}`,
 the end test for this loop is the predicate `\axiom{i > m}`.
 The body of the loop is evaluated `\axiom{m-n+1}` times if this
 number is greater than 0.
 If this number is less than or equal to 0, the loop body is not evaluated
 at all.

The variable `\axiom{i}` has the value
`\axiom{n, n+1, ..., m}` for successive iterations
 of the loop body.
 The loop variable is a `\spadgloss{local variable}`
 within the loop body: its value is not available outside the loop body
 and its value and type within the loop body completely mask any outer
 definition of a variable with the same name.

```
%

9.0.88 for i in n..m by s repeat

<ug05.ht>+≡

```
\begin{page}{ugLangLoopsForInNMSPage}{5.4.10. for i in n..m by s repeat}
\beginscroll
```

By default, the difference between values taken on by a variable in loops such as `\axiom{for i in n..m repeat ...}` is `\mathOrSpad{1}`.

It is possible to supply another, possibly negative, step value by using the `\axiom{by}`

`\spadkey{by}`

keyword along with `\axiom{for}` and `\axiom{in}`.

Like the upper and lower bounds, the step value following the `\axiom{by}` keyword must be an integer.

Note that the loop

```
\axiom{for i in 1..2 by 0 repeat output(i)}
```

will not terminate by itself, as the step value does not change the index from its initial value of `\mathOrSpad{1}`.

```

```
\begin{page}{ugLangLoopsForInNPage}{5.4.11. for i in n.. repeat}
\beginscroll
```

If the value after the `\axiomSyntax{..}`

is omitted, the loop has no end test.

A potentially infinite loop is thus created.

The variable is given the successive values `\axiom{n, n+1, n+2, ...}`

and the loop is terminated only if a `\axiom{break}` or `\axiom{return}` expression is evaluated in the loop body.

However you may also add some other modifying clause on the

`\axiom{repeat}` (for example, a `\axiom{while}` clause) to stop the loop.

```

```

9.0.90 for x in l repeat

<ug05.ht>+≡

```
\begin{page}{\ugLangLoopsForInXLPPage}{5.4.12. for x in l repeat}
\beginscroll
```

Another variant of the `\axiom{for}` loop has the form:

```
\centerline{{\it \axiom{for} x \axiom{in} list \axiom{repeat} loopBody}}}
```

This form is used when you want to iterate directly over the elements of a list.

In this form of the `\axiom{for}` loop, the variable

`\axiom{x}` takes on the value of each successive element in `\axiom{l}`.

The end test is most simply stated in English: ‘are there no more `\axiom{x}` in `\axiom{l}`?’

```
\xtc{
If \axiom{l} is this list,
}{
\spadpaste{l := [0,-5,3] \bound{l}}
}
\xtc{
display all elements of \axiom{l}, one per line.
}{
\spadpaste{for x in l repeat output(x) \free{l}}
}
```

Since the list constructing expression `\axiom{expand [n..m]}` creates the list `\axiom{[n, n+1, ..., m]}`^{\footnote{This list is empty if `\axiom{n > m}`.}}, you might be tempted to think that the loops

```
\begin{verbatim}
for i in n..m repeat output(i)
\end{verbatim}
and
\begin{verbatim}
for x in expand [n..m] repeat output(x)
\end{verbatim}
are equivalent.
```

The second form first creates the list

`\axiom{expand [n..m]}` (no matter how large it might be) and then does the iteration.

The first form potentially runs in much less space, as the index variable `\axiom{i}` is simply incremented once per loop and the list is not actually created.

Using the first form is much more efficient.

```
%
\xtc{
```

Of course, sometimes you really want to iterate across a specific list. This displays each of the factors of \axiom{2400000}.

```
{
\spadpaste{for f in factors(factor(2400000)) repeat output(f)}

9.0.91 “Such that” Predicates

`<ug05.ht>+≡`

```
\begin{page}{ugLangLoopsForInPredPage}{5.4.13. “Such that” Predicates}
\beginscroll
```

A `\axiom{for}` loop can be followed by a `\axiomSyntax{[]}` and then a predicate.

The predicate qualifies the use of the values from the iterator following the `\axiom{for}`.

Think of the vertical bar

`\axiomSyntax{[]}` as the phrase “such that.”

```
\xhc{
```

This loop expression

prints out the integers `\axiom{n}` in the given segment such that `\axiom{n}` is odd.

```
{
```

```
\spadpaste{for n in 0..4 | odd? n repeat output n}
```

```
}
```

```
\beginImportant
```

A `\axiom{for}` loop can also be written

```
\centerline{{\axiom{for} {\it iterator} \axiom{[]} {\it predicate}
```

```
\axiom{repeat} {\it loopBody}}}
```

which is equivalent to:

```
\centerline{{\axiom{for} {\it iterator} \axiom{repeat if}}}
```

```
\centerline{{{\it predicate} \axiom{then} {\it loopBody} \axiom{else}
```

```
\axiom{iterate}}}
```

```
\endImportant
```

The predicate need not refer only to the variable in the `\axiom{for}` clause: any variable in an outer scope can be part of the predicate.

```
\xhc{
```

In this example, the predicate on the inner `\axiom{for}` loop uses

`\axiom{i}` from the outer loop and the `\axiom{j}` from the `\axiom{for}`

clause that it directly modifies.

```
{
```

9.0.92 Parallel Iteration

⇒ “notitle” (ugLangLoopsForInPredPage) 9.0.91 on page 2018

ug05.ht+≡

```
\begin{page}{ugLangLoopsParPage}{5.4.14. Parallel Iteration}
\beginscroll
```

The last example of

```
\texht{the previous section}{
\downlink{‘‘Such that Predicates’’}{ugLangLoopsForInPredPage}
in Section 5.4.13\ignore{ugLangLoopsForInPred}}
gives an example of
```

```
\spadgloss{nested iteration}: a loop is contained
in another loop.
```

Sometimes you want to iterate across two lists in parallel, or perhaps you want to traverse a list while incrementing a variable.

```
\beginImportant
```

The general syntax of a repeat loop is

```
\centerline{{{ \tt \subscriptIt{iterator}{1} \subscriptIt{iterator}{2}
\ldots \subscriptIt{iterator}{N} repeat {\it loopBody}}}}
where each {\it iterator} is either a \axiom{for} or a \axiom{while} clause.
The loop terminates immediately when the end test of any {\it iterator}
succeeds or when a \axiom{break} or \axiom{return} expression is evaluated
in {\it loopBody}.
```

The value returned by the loop is \void{ }.

```
\endImportant
```

```
\xhc{
```

Here we write a loop to iterate across two lists, computing the sum of the pairwise product of elements. Here is the first list.

```
{
\spadpaste{l := [1,3,5,7] \bound{l}}
}
```

```
\xhc{
```

And the second.

```
{
\spadpaste{m := [100,200] \bound{m}}
}
```

```
\xhc{
```

The initial value of the sum counter.

```
{
\spadpaste{sum := 0 \bound{sum}}
```

```

}
\xtc{
The last two elements of \axiom{l} are not used in the calculation
because \axiom{m} has two fewer elements than \axiom{l}.
}{
\begin{spadsrc}[\bound{doit}\free{sum 1 m}]
for x in l for y in m repeat
    sum := sum + x*y
\end{spadsrc}
}
\xtc{
Display the ‘‘dot product.’’
}{
\spadpaste{sum \free{doit}}
}

\xtc{
Next, we write a loop to compute the sum of the products of the loop
elements with
their positions in the loop.
}{
\spadpaste{l := [2,3,5,7,11,13,17,19,23,29,31,37] \bound{l1}}
}
\xtc{
The initial sum.
}{
\spadpaste{sum := 0 \bound{sum1}}
}
\xtc{
Here looping stops when the list \axiom{l} is exhausted, even though
the \axiom{for i in 0..} specifies no terminating condition.
}{
\spadpaste{
for i in 0.. for x in l repeat sum := i * x \bound{doit1}\free{sum1 l1}}
}
\xtc{
Display this weighted sum.
}{
\spadpaste{sum \free{doit1}}
}

```

When `\axiomSyntax{}` is used to qualify any of the `\axiom{for}` clauses in a parallel iteration, the variables in the predicates can be from an outer scope or from a `\axiom{for}` clause in or to the left of a modified clause.

This is correct:

```

\begin{verbatim}
for i in 1..10 repeat
  for j in 200..300 | odd? (i+j) repeat
    output [i,j]
\end{verbatim}
This is not correct since the variable \axiom{j} has not been
defined outside the inner loop.
\begin{verbatim}
for i in 1..10 | odd? (i+j) repeat -- wrong, j not defined
  for j in 200..300 repeat
    output [i,j]
\end{verbatim}

%>\head{subsection}{Mixing Loop Modifiers}{ugLangLoopsMix}

\xtc{
This example shows that it is possible to mix several of the
forms of \axiom{repeat} modifying clauses on a loop.
}{
\begin{spadsrc}
for i in 1..10
  for j in 151..160 | odd? j
    while i + j < 160 repeat
      output [i,j]
\end{spadsrc}
}
%
Here are useful rules for composing loop expressions:
\indent{4}
\beginitems
\item[1. ] \axiom{while} predicates can only refer to variables that
are global (or in an outer scope)
or that are defined in \axiom{for} clauses to the left of the
predicate.
\item[2. ] A “such that” predicate (something following \axiomSyntax{||})
must directly follow a \axiom{for} clause and can only refer to
variables that are global (or in an outer scope)
or defined in the modified \axiom{for} clause
or any \axiom{for} clause to the left.

<ug05.ht>+≡

```
\begin{page}{ugLangItsPage}{5.5. Creating Lists and Streams with Iterators}
\beginscroll
```

All of what we did for loops in

```
\downlink{'Loops'}{ugLangLoopsPage}
```

in Section 5.4\ignore{ugLangLoops}

can be transformed into expressions that create lists and streams.

The `\axiom{repeat,}` `\axiom{break}` or `\axiom{iterate}` words are not used but all the other ideas carry over.

Before we give you the general rule, here are some examples which give you the idea.

```
\xctc{
```

This creates a simple list of the integers from `\axiom{1}` to `\axiom{10}`.

```
}{
```

```
\spadpaste{list := [i for i in 1..10] \bound{list}}
```

```
}
```

```
\xctc{
```

Create a stream of the integers greater than or equal to `\axiom{1}`.

```
}{
```

```
\spadpaste{stream := [i for i in 1..] \bound{stream}}
```

```
}
```

```
\xctc{
```

This is a list of the prime integers between `\axiom{1}` and `\axiom{10}`, inclusive.

```
}{
```

```
\spadpaste{[i for i in 1..10 | prime? i]}
```

```
}
```

```
\xctc{
```

This is a stream of the prime integers greater than or equal to `\axiom{1}`.

```
}{
```

```
\spadpaste{[i for i in 1.. | prime? i]}
```

```
}
```

```
\xctc{
```

This is a list of the integers between `\axiom{1}` and `\axiom{10}`, inclusive, whose squares are less than `\axiom{700}`.

```
}{
```

```

\spadpaste{[i for i in 1..10 while i*i < 700]}
}
\xtc{
This is a stream of the integers greater than or equal to \axiom{1}
whose squares are less than \axiom{700}.
}{
\spadpaste{[i for i in 1..    while i*i < 700]}
}

```

Got the idea?
Here is the general rule.

```

\beginImportant
The general syntax of a collection is
\centerline{{\tt [ {\it collectExpression} \subscriptIt{iterator}{1}
\subscriptIt{iterator}{2} \ldots \subscriptIt{iterator}{N} ]}}}
where each \subscriptIt{iterator}{i} is either a \axiom{for} or a
\axiom{while} clause.
The loop terminates immediately when the end test of any
\subscriptIt{iterator}{i} succeeds or when a \axiom{return} expression is
evaluated in {\it collectExpression}.
The value returned by the collection is either a list or a stream of
elements, one for each iteration of the {\it collectExpression}.
\endImportant

```

Be careful when you use \axiom{while}
to create a stream.
By default, Axiom tries to compute and display the first ten elements
of a stream.
If the \axiom{while} condition is not satisfied quickly, Axiom
can spend a long (possibly infinite) time trying to compute
the elements.
Use \spadcmd{set streams calculate} to change the default
to something else.
This also affects the number of terms computed and displayed for power
series.
For the purposes of this book, we have used this system
command to display fewer than ten terms.

```

\xtc{
Use nested iterators to create lists of
lists which can then be given as an argument to \axiomFun{matrix}.
}{
\spadpaste{matrix [[x**i+j for i in 1..3] for j in 10..12]}
}
\xtc{
You can also create lists of streams, streams of lists and

```

```

streams of streams.
Here is a stream of streams.
}{
\spadpaste{[[i/j for i in j+1..] for j in 1..]}
}
\xtc{
You can use parallel iteration across lists and streams to create
new lists.
}{
\spadpaste{[i/j for i in 3.. by 10 for j in 2..]}
}
\xtc{
Iteration stops if the end of a list or stream is reached.
}{
\spadpaste{[i**j for i in 1..7 for j in 2.. ]}
}
%\xtc{
%or a while condition fails.
%}{
%\spadcommand{[i**j for i in 1.. for j in 2.. while i + j < 5 ]}
%}
\xtc{
As with loops, you can combine these modifiers to make very
complicated conditions.
}{
\spadpaste{[[[i,j] for i in 10..15 | prime? i]
for j in 17..22 | j = squareFreePart j]]}
}

See \downlink{'List'}{ListXmpPage}\ignore{List} and
\downlink{'Stream'}{StreamXmpPage}\ignore{Stream}
for more information on creating and
manipulating lists and streams, respectively.

9.0.94 An Example: Streams of Primes

```

<ug05.ht>+≡
\begin{page}{ugLangStreamsPrimesPage}{5.6. An Example: Streams of Primes}
\beginscroll

```

We conclude this chapter with an example of the creation and manipulation of infinite streams of prime integers. This might be useful for experiments with numbers or other applications where you are using sequences of primes over and over again. As for all streams, the stream of primes is only computed as far out as you need. Once computed, however, all the primes up to that point are saved for future reference.

```

Two useful operations provided by the Axiom library are
\axiomFunFrom{prime?}{IntegerPrimesPackage} and
\axiomFunFrom{nextPrime}{IntegerPrimesPackage}.
A straight-forward way to create a stream of
prime numbers is to start with the stream of positive integers
\axiom{[2,..]} and filter out those that are prime.
\xtc{
Create a stream of primes.
}{
\spadpaste{primes : Stream Integer := [i for i in 2.. | prime? i]}
}
A more elegant way, however, is to use the \axiomFunFrom{generate}{Stream}
operation from \axiomType{Stream}.
Given an initial value \axiom{a} and a function \axiom{f},
\axiomFunFrom{generate}{Stream}
constructs the stream \axiom{[a, f(a), f(f(a)), ...]}.
This function gives you the quickest method of getting the stream of primes.
\xtc{
This is how you use
\axiomFunFrom{generate}{Stream} to
generate an infinite stream of primes.
}{
\spadpaste{primes := generate(nextPrime,2)}
}
\xtc{
Once the stream is generated, you might only be interested in
primes starting at a particular value.
}{
\spadpaste{smallPrimes := [p for p in primes | p > 1000]}
\bound{smallPrimes}}
}
\xtc{

```

```

Here are the first 11 primes greater than 1000.
}{
\spadpaste{[p for p in smallPrimes for i in 1..11] \free{smallPrimes}}
}
\xtc{
Here is a stream of primes between 1000 and 1200.
}{
\spadpaste{[p for p in smallPrimes while p < 1200] \free{smallPrimes}}
}
\xtc{
To get these expanded into a finite stream,
you call \axiomFunFrom{complete}{Stream} on the stream.
}{
\spadpaste{complete \%}
}
\xtc{
Twin primes are consecutive odd number pairs which are prime.
Here is the stream of twin primes.
}{
\spadpaste{twinPrimes := [[p,p+2] for p in primes | prime?(p + 2)]}
}
\xtc{
Since we already have the primes computed we can
avoid the call to \axiomFunFrom{prime?}{IntegerPrimesPackage}
by using a double iteration.
This time we'll just generate a stream of the first of the twin primes.
}{
\spadpaste{
firstOfTwins:= [p for p in primes for q in rest primes | q=p+2]}
}

Let's try to compute the infinite stream of triplet primes,
the set of primes \axiom{p} such that \axiom{[p,p+2,p+4]}
are primes. For example, \axiom{[3,5,7]} is a triple prime.
We could do this by a triple \axiom{for} iteration.
A more economical way is to use \userfun{firstOfTwins}.
This time however, put a semicolon at the end of the line.

\xtc{Create the stream of firstTriplets.
Put a semicolon at the end so that no
elements are computed.
}{
\spadpaste{firstTriplets :=
[p for p in firstOfTwins for q in rest firstOfTwins | q = p+2];}
}

```

What happened? As you know, by default Axiom displays the first ten elements of a stream when you first display it. And, therefore, it needs to compute them! If you want {\it no} elements computed, just terminate the expression by a semicolon (\axiomSyntax{;}).\footnote{Why does this happen? The semi-colon prevents the display of the result of evaluating the expression. Since no stream elements are needed for display (or anything else, so far), none are computed.}

```
\xctc{
Compute the first triplet prime.
}{
\spadpaste{firstTriplets.1}
}
```

If you want to compute another, just ask for it.
But wait a second!
Given three consecutive odd integers, one of them must be divisible by 3. Thus there is only one triplet prime.
But suppose that you did not know this and wanted to know what was the tenth triplet prime.

```
\begin{verbatim}
firstTriples.10
```

```
\end{verbatim}
```

To compute the tenth triplet prime, Axiom first must compute the second, the third, and so on.

But since there isn't even a second triplet prime, Axiom will compute forever.

Nonetheless, this effort can produce a useful result.

After waiting a bit, hit

```
\texht{\fbox{\bf Ctrl}--\fbox{\bf c}}{\bf Ctrl-c}.
```

The system responds as follows.

```
\begin{verbatim}
>> System error:
Console interrupt.
You are being returned to the top level of
the interpreter.
```

```
\end{verbatim}
```

Let's say that you want to know how many primes have been computed.

Issue

```
\begin{verbatim}
numberOfComputedEntries primes
\end{verbatim}
```

and, for this discussion, let's say that the result is \axiom{2045.}

```
\xctc{
```

How big is the \eth{\axiom{2045}} prime?

```

}{
\spadpaste{primes.2045}
}

```

What you have learned is that there are no triplet primes between 5 and 17837. Although this result is well known (some might even say trivial), there are many experiments you could make where the result is not known. What you see here is a paradigm for testing of hypotheses. Here our hypothesis could have been: “there is more than one triplet prime.” We have tested this hypothesis for 17837 cases. With streams, you can let your machine run, interrupt it to see how far it has progressed, then start it up and let it continue from where it left off.

```

In this chapter we show you how to write functions and macros, and we explain how Axiom looks for and applies them. We show some simple one-line examples of functions, together with larger ones that are defined piece-by-piece or through the use of files.

<ug06.ht>+≡

```
\begin{page}{ugUserFunMacPage}{6.1. Functions vs. Macros}
\beginscroll
```

A function is a program to perform some computation.

Most functions have names so that it is easy to refer to them.

A simple example of a function is one named

`\axiomFunFrom{abs}{Integer}` which computes the absolute value of an integer.

%

```
\xtc{
```

This is a use of the “absolute value” library function for integers.

```
}{
```

```
\spadpaste{abs(-8)}
```

```
}
```

```
\xtc{
```

This is an unnamed function that does the same thing, using the

“maps-to” syntax `\axiomSyntax{+>}` that we discuss in

`\downlink{‘Anonymous Functions’}{ugUserAnonPage}`

in Section 6.17`\ignore{ugUserAnon}`.

```
}{
```

```
\spadpaste{(x +> if x < 0 then -x else x)(-8)}
```

```
}
```

%

Functions can be used alone or serve as the building blocks for larger programs.

Usually they return a value that you might want to use in the next stage of a computation, but not always (for example, see

`\downlink{‘Exit’}{ExitXmpPage}\ignore{Exit}` and

`\downlink{‘Void’}{VoidXmpPage}\ignore{Void}`).

They may also read data from your keyboard, move information from one place to another, or format and display results on your screen.

In Axiom, as in mathematics, functions are usually

`\spadglossSee{parameterized}{parameterized form}`. Each time you `{\it call}` (some people say `\spadgloss{apply}` or

`\spadglossSee{invoke}{invocation}`) a function, you give values to the parameters (variables). Such a value is called an

`\spadgloss{argument}` of the function. Axiom uses the arguments for the computation. In this way you get different results depending on what you “feed” the function.

Functions can have local variables or refer to global variables in the workspace.

Axiom can often `\spadglossSee{compile}{compiler}` functions so that they execute very efficiently.

Functions can be passed as arguments to other functions.

Macros are textual substitutions. They are used to clarify the meaning of constants or expressions and to be templates for frequently used expressions. Macros can be parameterized but they are not objects that can be passed as arguments to functions. In effect, macros are extensions to the Axiom expression parser.

```

10.0.97 Macros

<ug06.ht>+≡

```
\begin{page}{ugUserMacrosPage}{6.2. Macros}
\beginscroll
```

A `\spadgloss{macro}` provides general textual substitution of an Axiom expression for a name.

You can think of a macro as being a generalized abbreviation.

You can only have one macro in your workspace with

a given name, no matter how many arguments it has.

```
\beginImportant
```

The two general forms for macros are

```
\centerline{{{ \tt macro} {\it name} {\tt ==} {\it body} }}
```

```
\centerline{{{ \tt macro} {\it name}(arg1,...)} {\tt ==} {\it body}}}
```

where the body of the macro can be any Axiom expression.

```
\endImportant
```

```
%
```

```
\xctc{
```

For example, suppose you decided that you

like to use `\axiom{df}` for `\axiomFun{D}`.

You define the macro `\axiom{df}` like this.

```
}{
```

```
\spadpaste{macro df == D \bound{df}}
```

```
}
```

```
\xctc{
```

Whenever you type `\axiom{df}`, the system expands it to

`\axiomFun{D}`.

```
}{
```

```
\spadpaste{df(x**2 + x + 1,x) \free{df}}
```

```
}
```

```
\xctc{
```

Macros can be parameterized and so can be used for many different

kinds of objects.

```
}{
```

```
\spadpaste{macro ff(x) == x**2 + 1 \bound{ff}}
```

```
}
```

```
\xctc{
```

Apply it to a number, a symbol, or an expression.

```
}{
```

```
\spadpaste{ff z \free{ff}}
```

```
}
```

```
\xctc{
```

Macros can also be nested, but you get an error message if you

```

run out of space because of an infinite nesting loop.
}{
\spadpaste{macro gg(x) == ff(2*x - 2/3) \bound{gg}\free{ff}}
}
\xtc{
This new macro is fine as it does not produce a loop.
}{
\spadpaste{gg(1/w) \free{gg}}
}
%
\xtc{
This, however, loops since \axiom{gg} is
defined in terms of \axiom{ff}.
}{
\spadpaste{macro ff(x) == gg(-x) \free{gg}}
}
\xtc{
The body of a macro can be a block.
}{
\spadpaste{macro next == (past := present; present := future;
future := past + present) \bound{next}}
}
\xtc{
Before entering \axiom{next}, we need
values for \axiom{present} and \axiom{future}.
}{
\spadpaste{present : Integer := 0 \bound{present}}
}
\xtc{
}{
\spadpaste{future : Integer := 1 \bound{future}}
}
\xtc{
Repeatedly evaluating \axiom{next} produces the next Fibonacci number.
}{
\spadpaste{next \free{future}\free{present}}
}
\xtc{
And the next one.
}{
\spadpaste{next \free{future}\free{present}}
}
\xtc{
Here is the infinite stream of the rest of the Fibonacci numbers.
}{
\spadpaste{[next for i in 1..] \free{future}\free{present}}
}

```

```

}
\xtc{
Bundle all the above lines into a single macro.
}{
\begin{spadsrc}[\bound{fibstr}]
macro fibStream ==
  present : Integer := 1
  future : Integer := 1
  [next for i in 1..] where
    macro next ==
      past := present
      present := future
      future := past + present
\end{spadsrc}
}
\xtc{
Use \axiomFunFrom{concat}{Stream} to start with the first two
Fibonacci numbers.
}{
\spadpaste{concat([0,1],fibStream) \free{fibstr}}
}
\xtc{
An easier way to compute these numbers is to
use the library operation \axiomFun{fibonacci}.
}{
\spadpaste{[fibonacci i for i in 1..]}
}

10.0.98 Introduction to Functions

⇒ “notitle” (ugTypesPkgCallPage) 7.0.52 on page 1882

⇒ “notitle” (ugUserAnonPage) 10.0.115 on page 2157

<ug06.ht>+≡

```
\begin{page}{ugUserIntroPage}{6.3. Introduction to Functions}
\beginscroll
```

Each name in your workspace can refer to a single object.

This may be any kind of object including a function.

You can use interactively any function from the library or any that you define in the workspace.

In the library the same name can have very many functions, but you can have only one function with a given name, although it can have any number of arguments that you choose.

If you define a function in the workspace that has the same name and number of arguments as one in the library, then your definition takes precedence.

In fact, to get the library function you must

```
\spadglossSee{package-call}{package call} it (see
\downlink{‘‘Package Calling and Target Types’’}{ugTypesPkgCallPage}
in Section 2.9\ignore{ugTypesPkgCall}).
```

To use a function in Axiom, you apply it to its arguments.

Most functions are applied by entering the name of the function followed by its argument or arguments.

```
\xtc{
}{
\spadpaste{factor(12)}
}
%
```

```
\xtc{
```

Some functions like

`\axiomOp{+}` have `{\it infix}` `\spadgloss{operators}` as names.

```
{
\spadpaste{3 + 4}
}
```

```
\xtc{
```

The function `\axiomOp{+}` has two arguments.

When you give it more than two arguments,

Axiom groups the arguments to the left.

This expression is equivalent to `\axiom{(1 + 2) + 7}`.

```
{
\spadpaste{1 + 2 + 7}
```

}

All operations, including infix operators, can be written in prefix form, that is, with the operation name followed by the arguments in parentheses.

For example, `\axiom{2 + 3}` can alternatively be written as `\axiom{+(2,3)}`. But `\axiom{+(2,3,4)}` is an error since `\axiomOp{+}` takes only two arguments.

Prefix operations are generally applied before the infix operation. Thus `\axiom{factorial 3 + 1}` means `\axiom{factorial(3) + 1}` producing `\axiom{7}`, and

`\axiom{- 2 + 5}` means `\axiom{(-2) + 5}` producing `\axiom{3}`.

An example of a prefix operator is prefix `\axiomOp{-}`.

For example, `\axiom{- 2 + 5}` converts to `\axiom{(- 2) + 5}` producing the value `\axiom{3}`.

Any prefix function taking two arguments can be written in an infix manner by putting an ampersand (`\axiomSyntax{&}`) before the name.

Thus `\axiom{D(2*x,x)}` can be written as `\axiom{2*x &D x}` returning `\axiom{2}`.

Every function in Axiom is identified by a `\spadgloss{name}` and `\spadgloss{type}`.^{[\footnote{An exception is an ‘anonymous function’}](#)}

discussed in

`\downlink{‘Anonymous Functions’}{ugUserAnonPage}`
in Section 6.17`\ignore{ugUserAnon}.`

The type of a function is always a mapping of the form `\spadsig{Source}{Target}`

where `\axiom{Source}` and `\axiom{Target}` are types.

To enter a type from the keyboard, enter the arrow by using a hyphen `\axiomSyntax{-}` followed by a greater-than sign `\axiomSyntax{>}`, e.g. `{\tt Integer -> Integer}`.

Let's go back to `\axiomOp{+}`.

There are many `\axiomOp{+}` functions in the Axiom library: one for integers, one for floats, another for rational numbers, and so on.

These `\axiomOp{+}` functions have different types and thus are different functions.

You've seen examples of this `\spadgloss{overloading}` before---using the same name for different functions.

Overloading is the rule rather than the exception.

You can add two integers, two polynomials, two matrices or two power series.

These are all done with the same function name
but with different functions.

10.0.99 Declaring the Type of Functions

⇒ “notitle” (ugTypesDeclarePage) 7.0.44 on page 1829

<ug06.ht>+≡

```
\begin{page}{ugUserDeclarePage}{6.4. Declaring the Type of Functions}
\beginscroll
```

In `\downlink{‘‘Declarations’’}{ugTypesDeclarePage}` in Section 2.3`\ignore{ugTypesDeclare}` we discussed how to declare a variable to restrict the kind of values that can be assigned to it. In this section we show how to declare a variable that refers to function objects.

```
\beginImportant
A function is an object of type
\centerline{{\spadsig{Source}{Type}}}
where \axiom{Source} and \axiom{Target} can be any type.
A common type for \axiom{Source} is
\axiomType{Tuple}(\subscriptIt{T}{1}, \ldots, \subscriptIt{T}{n}),
usually written
(\subscriptIt{T}{1}, \ldots, \subscriptIt{T}{n}),
to indicate a function of \axiom{n} arguments.
\endImportant
```

```
\xctc{
If \axiom{g} takes an \axiomType{Integer}, a \axiomType{Float} and
another \axiomType{Integer}, and returns a
\axiomType{String}, the declaration is written this way.
}{
\spadpaste{g: (Integer,Float,Integer) -> String}
}
\xctc{
The types need not be written fully; using abbreviations, the above
declaration is:
}{
\spadpaste{g: (INT,FLOAT,INT) -> STRING}
}
\xctc{
It is possible for a function to take no arguments.
If \axiom{h} takes no arguments
but returns a \axiomType{Polynomial} \axiomType{Integer}, any
of the following declarations is acceptable.
}{
```

```

\spadpaste{h: () -> POLY INT}
}
\xtc{
}{
\spadpaste{h: () -> Polynomial INT}
}
\xtc{
}{
\spadpaste{h: () -> POLY Integer}
}

```

```

\beginImportant

```

Functions can also be declared when they are being defined.
The syntax for combined declaration/definition is:

```

\centerline{{\frenchspacing{\tt {\it functionName}(
\subscriptIt{parm}{1}: \subscriptIt{parmType}{1}, \ldots,
\subscriptIt{parm}{N}: \subscriptIt{parmType}{N}):
{\it functionReturnType}}}}
\endImportant

```

The following definition fragments show how this can be done for
the functions `\axiom{g}` and `\axiom{h}` above.

```

\begin{verbatim}
g(arg1: INT, arg2: FLOAT, arg3: INT): STRING == ...

h(): POLY INT == ...
\end{verbatim}

```

A current restriction on function declarations is that they must
involve fully specified types (that is, cannot include modes involving
explicit or implicit `\axiomSyntax{?}`).

For more information on declaring things in general, see
`\downlink{'Declarations'}{ugTypesDeclarePage}`
in Section 2.3`\ignore{ugTypesDeclare}`.

10.0.100 One-Line Functions

```

<ug06.ht>+≡
\begin{page}{ugUserOnePage}{6.5. One-Line Functions}
\beginscroll

```

As you use Axiom, you will find that you will write many short functions to codify sequences of operations that you often perform. In this section we write some simple one-line functions.

```

\xtc{
This is a simple recursive factorial function for positive integers.
}{
\spadpaste{fac n == if n < 3 then n else n * fac(n-1) \bound{fac}}
}
\xtc{
}{
\spadpaste{fac 10 \free{fac}}
}
%>> Thankfully, the $ is no longer needed in the next example.
\xtc{
This function computes \axiom{1 + 1/2 + 1/3 + ... + 1/n}.
}{
\spadpaste{s n == reduce(+,[1/i for i in 1..n]) \bound{s}}
}
\xtc{
}{
\spadpaste{s 50 \free{s}}
}
\xtc{
This function computes a Mersenne number, several of which are prime.
}{
\spadpaste{mersenne i == 2**i - 1 \bound{mersenne}}
}
\xtc{
If you type \axiom{mersenne}, Axiom shows you
the function definition.
}{
\spadpaste{mersenne \free{mersenne}}
}
\xtc{
Generate a stream of Mersenne numbers.
}{
\spadpaste{[mersenne i for i in 1..] \free{mersenne}}
}
\xtc{

```

```

Create a stream of those values of \axiom{i} such that
\axiom{mersenne(i)} is prime.
}{
\spadpaste{mersenneIndex := [n for n in 1.. | prime?(mersenne(n))]}
\bound{mersenneIndex}\free{mersenne}
}
\xtc{
Finally, write a function that returns the \eth{\axiom{n}} Mersenne
prime.
}{
\spadpaste{mersennePrime n == mersenne mersenneIndex(n)}
\free{mersenne mersenneIndex}\bound{mersennePrime}
}
\xtc{
}{
\spadpaste{mersennePrime 5 \free{mersennePrime}}
}

10.0.101 Declared vs. Undeclared Functions

⇒ “notitle” (ugCategoriesPage) 15.0.209 on page 2709

```

<ug06.ht>+≡
\begin{page}{ugUserDecUndecPage}{6.6. Declared vs. Undeclared Functions}
\beginscroll

```

If you declare the type of a function, you can apply it to any data that can be converted to the source type of the function.

```

\labelSpace{2pc}
\xtc{
Define \userfun{f} with type \spadsig{Integer}{Integer}.
}{
\spadpaste{f(x: Integer): Integer == x + 1 \bound{f}}
}
\xtc{
The function
\userfun{f} can be applied to integers, \ldots
}{
\spadpaste{f 9 \free{f}}
}
\xtc{
and to values that convert to integers, \ldots
}{
\spadpaste{f(-2.0) \free{f}}
}
\xtc{
but not to values that cannot be converted to integers.
}{
\spadpaste{f(2/3) \free{f}}
}

```

To make the function over a wide range of types, do not declare its type.

```

\xtc{
Give the same definition with no declaration.
}{
\spadpaste{g x == x + 1 \bound{g}}
}
\xtc{
If \axiom{x + 1} makes sense, you can apply \userfun{g} to \axiom{x}.
}{

```

```

\spadpaste{g 9 \free{g}}
}
\xtc{
A version of \userfun{g} with different argument types
get compiled for each new kind of argument used.
}{
\spadpaste{g(2/3) \free{g}}
}
\xtc{
Here \axiom{x+1} for \axiom{x = "axiom"} makes no sense.
}{
\spadpaste{g("axiom")\free{g}}
}

10.0.102 Functions vs. Operations

⇒ “notitle” (MappingPackageOneXmpPage) 3.73.1 on page 1072

⇒ “notitle” (ugPackagesAbstractPage) 14.0.201 on page 2683

⇒ “notitle” (ugPackagesPage) 14.0.198 on page 2677

⇒ “notitle” (ugCategoriesPage) 15.0.209 on page 2709

`\ug06.ht`+≡

`\begin{page}{ugUserDecOpsPage}{6.7. Functions vs. Operations}`

`\beginscroll`

A function is an object that you can create, manipulate, pass to, and return from functions (for some interesting examples of library functions that manipulate functions, see

`\downlink{‘MappingPackage1’}{MappingPackageOneXmpPage}`

`\ignore{MappingPackage1}`).

Yet, we often seem to use the term `\spadgloss{operation}` and function interchangeably in Axiom.

What is the distinction?

First consider values and types associated with some variable

`\axiom{n}` in your workspace. You can make the declaration `\axiom{n : Integer}`, then assign `\axiom{n}` an integer value. You then speak of the integer `\axiom{n}`. However, note that the integer is not the name `\axiom{n}` itself, but the value that you assign to `\axiom{n}`.

Similarly, you can declare a variable `\axiom{f}` in your workspace to have type `\spadsig{Integer}{Integer}`, then assign `\axiom{f}`, through a definition or an assignment of an anonymous function. You then speak of the function `\axiom{f}`. However, the function is not `\axiom{f}`, but the value that you assign to `\axiom{f}`.

A function is a value, in fact, some machine code for doing something. Doing what? Well, performing some `\spadgloss{operation}`. Formally, an operation consists of the constituent parts of `\axiom{f}` in your workspace, excluding the value; thus an operation has a name and a type. An operation is what domains and packages export. Thus `\axiomType{Ring}` exports one operation `\axiomOp{+}`. Every ring also exports this operation. Also, the author of every ring in the system is obliged under contract (see `\downlink{‘Abstract Datatypes’}{ugPackagesAbstractPage}` in Section 11.3`\ignore{ugPackagesAbstract}`) to provide an implementation for this operation.

This chapter is all about functions---how you create them

interactively and how you apply them to meet your needs. In
`\downlink{'Packages'}{ugPackagesPage}` in Chapter
11`\ignore{ugPackages}` you will learn how to create them
for the Axiom library. Then in
`\downlink{'Categories'}{ugCategoriesPage}` in Chapter
12`\ignore{ugCategories}`, you will learn about
categories and exported operations.

10.0.103 Delayed Assignments vs. Functions with No Arguments

⇒ “notitle” (ugLangAssignPage) 9.0.75 on page 1952

`<ug06.ht>+≡`

```
\begin{page}{ugUserDelayPage}
{6.8. Delayed Assignments vs. Functions with No Arguments}
\beginscroll
```

In `\downlink{‘‘Immediate and Delayed Assignments’’}`
`{ugLangAssignPage}` in Section
 5.1`\ignore{ugLangAssign}` we discussed the difference
 between immediate and
 delayed assignments.
 In this section we show the difference between delayed
 assignments and functions of no arguments.

```
\labelSpace{2pc}
\xtc{
A function of no arguments is sometimes called a {\it nullary function.}
}{
\spadpaste{sin24() == sin(24.0) \bound{sin24}}
}
\xtc{
You must use the parentheses (\axiomSyntax{()}) to evaluate it.
Like a delayed assignment, the right-hand-side of a function evaluation
is not evaluated until the left-hand-side is used.
}{
\spadpaste{sin24() \free{sin24}}
}
\xtc{
If you omit the parentheses, you just get the function definition.
%(Note how the explicit floating point number in the definition
%has been translated into a function call involving a mantissa,
%exponent and radix.)
}{
\spadpaste{sin24 \free{sin24}}
}
\xtc{
You do not use the parentheses \axiomSyntax{()} in a
delayed assignment\ldots
}{
\spadpaste{cos24 == cos(24.0) \bound{cos24}}
}
}
```

```

\xtc{
nor in the evaluation.
}{
\spadpaste{cos24 \free{cos24}}
}

```

The only syntactic difference between delayed assignments and nullary functions is that you use `\axiomSyntax{() }` in the latter case.

10.0.104 How Axiom Determines What Function to Use

⇒ “notitle” (ugTypesPkgCallPage) 7.0.52 on page 1882

⇒ “notitle” (ugTypesResolvePage) 7.0.53 on page 1892

`<ug06.ht>+≡`

```
\begin{page}{ugUserUsePage}
{6.9. How Axiom Determines What Function to Use}
\beginscroll
```

What happens if you define a function that has the same name as a library function? Well, if your function has the same name and number of arguments (we sometimes say `\spadgloss{arity}`) as another function in the library, then your function covers up the library function. If you want then to call the library function, you will have to package-call it. Axiom can use both the functions you write and those that come from the library. Let's do a simple example to illustrate this.

```
\xtc{
Suppose you (wrongly!) define \userfun{sin} in this way.
}{
\spadpaste{sin x == 1.0 \bound{sin}}
}
\xtc{
The value \axiom{1.0} is returned for any argument.
}{
\spadpaste{sin 4.3 \free{sin}}
}
\xtc{
If you want the library operation, we have to package-call it
(see \downlink{'Package Calling and Target Types'}{ugTypesPkgCallPage}
in Section 2.9\ignore{ugTypesPkgCall}
for more information).
}{
\spadpaste{sin(4.3)\$Float}
}
\xtc{
}{
\spadpaste{sin(34.6)\$Float}
}
\xtc{
Even worse, say we accidentally used the same name as a library
function in the function.
}{
\spadpaste{sin x == sin x \bound{sin1}}
```

```

}
\xtc{
Then Axiom definitely does not understand us.
}{
\spadpaste{sin 4.3 \free{sin1}}
}
\xtc{
Again, we could package-call the inside function.
}{
\spadpaste{sin x == sin(x)\$Float \bound{sin2}}
}
\xtc{
}{
\spadpaste{sin 4.3 \free{sin2}}
}

```

Of course, you are unlikely to make such obvious errors.
It is more probable that you would write a function and in the body use a
function that you think is a library function.
If you had also written a function by that same name, the library function
would be invisible.

How does Axiom determine what library function to call?

It very much depends on the particular example, but the simple case of
creating the polynomial
\axiom{x + 2/3} will give you an idea.

```

\indent{4}
\beginitems
\item[1. ] The \axiom{x} is analyzed and its default type is
\axiomType{Variable(x)}.
\item[2. ] The \axiom{2} is analyzed and its default type is
\axiomType{PositiveInteger}.
\item[3. ] The \axiom{3} is analyzed and its default type is
\axiomType{PositiveInteger}.
\item[4. ] Because the arguments to \axiomOp{/} are integers, Axiom
gives the expression \axiom{2/3} a default target type of
\axiomType{Fraction(Integer)}.
\item[5. ] Axiom looks in \axiomType{PositiveInteger} for \axiomOp{/}.
It is not found.
\item[6. ] Axiom looks in \axiomType{Fraction(Integer)} for \axiomOp{/}.
It is found for arguments of type \axiomType{Integer}.
\item[7. ] The \axiom{2} and \axiom{3} are converted to objects of type
\axiomType{Integer} (this is trivial) and \axiomOp{/} is applied,
creating an object of type \axiomType{Fraction(Integer)}.
\item[8. ] No \axiomOp{+} for arguments of types \axiomType{Variable(x)}
and \axiomType{Fraction(Integer)} are found in either domain.
\item[9. ] Axiom resolves

```

```

(see \downlink{'Resolving Types'}{ugTypesResolvePage}
in Section 2.10\ignore{ugTypesResolve})
the types and gets \axiomType{Polynomial (Fraction (Integer))}.
\item[10. ] The \axiom{x} and the \axiom{2/3} are converted to objects
of this type and \axiomOp{+} is applied, yielding the answer, an object
of type \axiomType{Polynomial (Fraction (Integer))}.

10.0.105 Compiling vs. Interpreting

⇒ “notitle” (ugTypesSubdomainsPage) 7.0.51 on page 1874

<ug06.ht>+≡

```
\begin{page}{ugUserCompIntPage}{6.10. Compiling vs. Interpreting}
\beginscroll
```

When possible, Axiom completely determines the type of every object in a function, then translates the function definition to `\Lisp{}` or to machine code (see next section). This translation, called `\spadglossSee{compilation}{compiler}`, happens the first time you call the function and results in a computational delay. Subsequent function calls with the same argument types use the compiled version of the code without delay.

If Axiom cannot determine the type of everything, the function may still be executed but in `\spadglossSee{interpret-code mode}{interpreter}` : each statement in the function is analyzed and executed as the control flow indicates. This process is slower than executing a compiled function, but it allows the execution of code that may involve objects whose types change.

```
\beginImportant
```

If Axiom decides that it cannot compile the code, it issues a message stating the problem and then the following message:

```
%
\centerline{
{\bf We will attempt to step through and interpret the code.}}}
%
```

This is not a time to panic.

Rather, it just means that what you gave to Axiom is somehow ambiguous: either it is not specific enough to be analyzed completely, or it is beyond Axiom’s present interactive compilation abilities.

```
\endImportant
```

```
\xtc{
```

This function runs in `interpret-code` mode, but it does not compile.

```
}{
```

```
\begin{spadsrc}{\bound{varPolys}}
```

```
varPolys(vars) ==
```

```
  for var in vars repeat
```

```
    output(1 :: UnivariatePolynomial(var,Integer))
```

```

\end{spadsrc}
}
\xtc{
For \axiom{vars} equal to \axiom{['x, 'y, 'z]}, this function displays
\axiom{1} three times.
}{
\spadpaste{varPolys ['x,'y,'z] \free{varPolys}}
}
\xtc{
The type of the argument to \axiomFun{output} changes in each iteration,
so Axiom cannot compile the function.
In this case, even the inner loop by itself would have a problem:
}{
\begin{spadsrc}
for var in ['x,'y,'z] repeat
    output(1 :: UnivariatePolynomial(var,Integer))
\end{spadsrc}
}

```

Sometimes you can help a function to compile by using an extra conversion or by using `\axiom{pretend}`. `\spadkey{pretend}` See `\downlink{'Subdomains Again'}{ugTypesSubdomainsPage}` in Section 2.8\ignore{ugTypesSubdomains} for details.

When a function is compilable, you have the choice of whether it is compiled to `\Lisp{}` and then interpreted by the `\Lisp{}` interpreter or then further compiled from `\Lisp{}` to machine code. The option is controlled via `\spadcmd{set functions compile}`. Issue `\spadcmd{set functions compile on}` to compile all the way to machine code. With the default setting `\spadcmd{set functions compile off}`, Axiom has its `\Lisp{}` code interpreted because the overhead of further compilation is larger than the run-time of most of the functions our users have defined. You may find that selectively turning this option on and off will give you the best performance in your particular application. For example, if you are writing functions for graphics applications where hundreds of points are being computed, it is almost certainly true that you will get the best performance by issuing `\spadcmd{set functions compile on}`.

10.0.107 A Basic Example

<ug06.ht>+≡

```
\begin{page}{ugUserPieceBasicPage}{6.11.1. A Basic Example}
\beginscroll
```

There are many other ways to define a factorial function for nonnegative integers.

You might

say

factorial of $\text{\axiom{0}}$ is $\text{\axiom{1}}$, otherwise factorial of $\text{\axiom{n}}$ is $\text{\axiom{n}}$ times factorial of $\text{\axiom{n-1}}$.

Here is one way to do this in Axiom.

```
%
```

```
\xtc{
```

```
Here is the value for \axiom{n = 0}.
```

```
}{
```

```
\spadpaste{fact(0) == 1 \bound{fact0}}
```

```
}
```

```
\xtc{
```

```
Here is the value for \axiom{n > 0}.
```

```
The vertical bar \axiomSyntax{|} means
```

```
‘‘such that’’.
```

```
}{
```

```
\spadpaste{fact(n | n > 0) == n * fact(n - 1) \free{fact0}\bound{factn}}
```

```
}
```

```
\xtc{
```

```
What is the value for \axiom{n = 3}?
```

```
}{
```

```
\spadpaste{fact(3) \free{factn}}
```

```
}
```

```
\xtc{
```

```
What is the value for \axiom{n = -3}?
```

```
}{
```

```
\spadpaste{fact(-3) \free{factn}}
```

```
}
```

```
\xtc{
```

```
Now for a second definition.
```

```
Here is the value for \axiom{n = 0}.
```

```
}{
```

```
\spadpaste{facto(0) == 1 \bound{facto0}}
```

```
}
```

```
\xtc{
```

```
Give an error message if \axiom{n < 0}.
```

```
}{
```

```
\spadpaste{facto(n | n < 0) ==
```

```

error "arguments to facto must be non-negative"
\free{facto0}\bound{factop}}
}
\xtc{
Here is the value otherwise.
}{
\spadpaste{facto(n) == n * facto(n - 1) \free{factop}\bound{facton}}
}
\xtc{
What is the value for \axiom{n = 7}?
}{
\spadpaste{facto(7) \free{facton}}
}
\xtc{
What is the value for \axiom{n = -7}?
}{
\spadpaste{facto(-7) \free{facton}}
}
\xtc{
To see the current piece-wise definition of a function,
use \spadsys{}display value}.
}{
\spadpaste{}display value facto \free{facton}}
}

```

In general a {\it piece-wise definition} of a function consists of two or more parts. Each part gives a ‘‘piece’’ of the entire definition. Axiom collects the pieces of a function as you enter them. When you ask for a value of the function, it then ‘‘glues’’ the pieces together to form a function.

The two piece-wise definitions for the factorial function are examples of recursive functions, that is, functions that are defined in terms of themselves. Here is an interesting doubly-recursive function. This function returns the value \axiom{11} for all positive integer arguments.

```

\xtc{
Here is the first of two pieces.
}{
\spadpaste{eleven(n | n < 1) == n + 11\bound{ff0}}
}
\xtc{
And the general case.
}{
\spadpaste{eleven(m) == eleven(eleven(m - 12))\bound{ff1}\free{ff0}}
}

```

```

\xtc{
Compute \axiom{elevens}, the infinite stream
of values of \axiom{eleven}.
}{
\spadpaste{elevens := [eleven(i) for i in 0..]\bound{ff2}\free{ff1}}
}
\xtc{
What is the value at \axiom{n = 200}?
}{
\spadpaste{elevens 200\free{ff2}}
}
\xtc{
What is the Axiom's definition of \axiom{eleven}?
}{
\spadpaste{}display value eleven\free{ff2}}
}
\endscroll

10.0.108 Picking Up the Pieces

⇒ “notitle” (ugUserPieceBasicPage) 10.0.107 on page 2089

<ug06.ht>+≡

```
\begin{page}{ugUserPiecePickingPage}{6.11.2. Picking Up the Pieces}
\beginscroll
```

Here are the details about how Axiom creates a function from its pieces. Axiom converts the `\eth{\axiom{i}}` piece of a function definition into a conditional expression of the form: `\axiom{if} \pred{i} \axiom{then} \expr{i}`. If any new piece has a `\pred{i}` that is identical^{\footnote{after all variables are uniformly named}} to an earlier `\pred{j}`, the earlier piece is removed. Otherwise, the new piece is always added at the end.

```
\beginImportant
If there are \axiom{n} pieces to a function definition for \axiom{f},
the function defined \axiom{f} is: \newline
%
\texht{\hspace*{3pc}}{\tab{6}}
{\tt if} \pred{1} {\tt then} \expr{1} {\tt else}\newline
\texht{\hspace*{6pc}}{\tab{12}}. . . \newline
\texht{\hspace*{3pc}}{\tab{6}}
{\tt if} \pred{n} {\tt then} \expr{n} {\tt else}\newline
\texht{\hspace*{3pc}}{\tab{6}}
{\tt error "You did not define f for argument <arg>."}
%
\endImportant
```

You can give definitions of any number of mutually recursive function definitions, piece-wise or otherwise. No computation is done until you ask for a value. When you do ask for a value, all the relevant definitions are gathered, analyzed, and translated into separate functions and compiled.

```
\xctc{
Let's recall the definition of \userfun{eleven} from
\texht{the previous section}{
\downlink{'A Basic Example'}{ugUserPieceBasicPage}
in Section 6.11.1\ignore{ugUserPieceBasic}}.
}{
\spadpaste{eleven(n | n < 1) == n + 11\bound{ff0}}
}
\xctc{
```

```

}{
\spadpaste{eleven(m) == eleven(eleven(m - 12))\bound{ff1}\free{ff0}}
}

```

A similar doubly-recursive function below produces `\axiom{-11}` for all negative positive integers. If you haven't worked out why or how `\userfun{eleven}` works, the structure of this definition gives a clue.

```
\xctc{
```

This definition we write as a block.

```

}{
\begin{spadsrc}[\bound{rf1}]
minusEleven(n) ==
  n >= 0 => n - 11
  minusEleven (5 + minusEleven(n + 7))
\end{spadsrc}
}

```

```
\xctc{
```

Define `\axiom{s(n)}` to be the sum of plus and minus ‘eleven’ functions divided by `\axiom{n}`. Since `\axiom{11 - 11 = 0}`, we define `\axiom{s(0)}` to be `\axiom{1}`.

```

}{
\spadpaste{s(0) == 1\bound{rf2}}
}

```

```
\xctc{
```

And the general term.

```

}{
\spadpaste{s(n) == (eleven(n) + minusEleven(n))/n
\bound{rf3}\free{rf2 rf1 ff1}}
}

```

```
\xctc{
```

What are the first ten values of `\axiom{s}`?

```

}{
\spadpaste{[s(n) for n in 0..]\free{rf3}}
}

```

%% interpreter puts the rule at the end - should fix

Axiom can create infinite streams in the positive direction (for example, for index values `\axiom{0,1, \ldots}`) or negative direction (for example, for index values `\axiom{0,-1,-2, \ldots}`). Here we would like a stream of values of `\axiom{s(n)}` that is infinite in both directions. The function `\axiom{t(n)}` below returns the `\eth{\axiom{n}}` term of the infinite stream `\axiom{[s(0), s(1), s(-1), s(2), s(-2), \ldots]}`. Its definition has three pieces.

```
\xctc{
```

Define the initial term.

```

}{
\spadpaste{t(1) == s(0)\bound{t1}\free{rf4}}
}

```

```

}
\xtc{
The even numbered terms are the \axiom{s(i)} for positive \axiom{i}.
We use \axiomOp{quo} rather than \axiomOp{/}
since we want the result to be an integer.
}{
\spadpaste{t(n | even?(n)) == s(n quo 2)\free{t1}\bound{t2}}
}
\xtc{
Finally, the odd numbered terms are the
\axiom{s(i)} for negative \axiom{i}.
In piece-wise definitions, you can use different variables
to define different pieces. Axiom will not get confused.
}{
\spadpaste{t(p) == s(- p quo 2)\free{t2}\bound{t3}}
}
\xtc{
Look at the definition of \axiom{t}.
In the first piece, the variable \axiom{n}
was used; in the second piece, \axiom{p}.
Axiom always uses
your last variable to display your definitions
back to you.
}{
\spadpaste{display value t\free{t2}}
}
\xtc{
Create a series of values of \axiom{s} applied to
alternating positive and negative arguments.
}{
\spadpaste{[t(i) for i in 1..]\free{t3}\bound{t4}}
}
\xtc{
Evidently \axiom{t(n) = 1} for all \axiom{i}.
Check it at \axiom{n= 100}.
}{
\spadpaste{t(100)\free{t4}}
}

10.0.109 Predicates

⇒ “notitle” (ugUserPieceBasicPage) 10.0.107 on page 2089

```
<ug06.ht>+≡
\begin{page}{ugUserPiecePredPage}{6.11.3. Predicates}
\beginscroll
```

We have already seen some examples of predicates
`(\downlink{‘‘A Basic Example’’}{ugUserPieceBasicPage}`
in Section 6.11.1\ignore{ugUserPieceBasic}).
Predicates are `\axiomType{Boolean}`-valued expressions and Axiom uses them
for filtering collections
(see `\downlink{‘‘Creating Lists and Streams with Iterators’’}`
`{ugLangItsPage}` in Section 5.5\ignore{ugLangIts})
and for placing constraints on function arguments.
In this section we discuss their latter usage.

```
\xctc{
The simplest use of a predicate is one you don't see at all.
}{
\spadpaste{opposite 'right == 'left}
}
\xctc{
Here is a longer way to give the ‘‘opposite definition.’’
}{
\spadpaste{opposite (x | x = 'left) == 'right}
}
\xctc{
Try it out.
}{
\spadpaste{for x in ['right,'left,'inbetween] repeat output opposite x}
}
```

Explicit predicates tell Axiom that the given function definition
piece is to be applied if the predicate evaluates to `{\tt true}` for
the arguments to the function. You can use such “constant”
arguments for integers, strings, and quoted symbols. The
`\axiomType{Boolean}` values `\axiom{true}` and `\axiom{false}` can also be
used if qualified with “`\spad{@}`” or “`\spad{\$}`” and
`\axiomType{Boolean}`. The following are all valid function definition
fragments using constant arguments.
`\begin{verbatim}`
`a(1) == ...`

```

b("unramified") == ...
c('untested') == ...
d(true@Boolean) == ...
\end{verbatim}

```

If a function has more than one argument, each argument can have its own predicate. However, if a predicate involves two or more arguments, it must be given `\it after` all the arguments mentioned in the predicate have been given. You are always safe to give a single predicate at the end of the argument list.

```

\xtc{
A function involving predicates on two arguments.
}{
\spadpaste{inFirstHalfQuadrant(x | x > 0,y | y < x) == true}
}
\xtc{
This is incorrect as it gives a predicate on \axiom{y}
before the argument \axiom{y} is given.
}{
\spadpaste{inFirstHalfQuadrant(x | x > 0 and y < x,y) == true}
}
\xtc{
It is always correct to write the predicate at the end.
}{
\spadpaste{inFirstHalfQuadrant(x,y | x > 0 and y < x) == true \bound{ifq1a}}
}
\xtc{
Here is the rest of the definition.
}{
\spadpaste{inFirstHalfQuadrant(x,y) == false \bound{ifq1b}}
}
\xtc{
Try it out.
}{
\spadpaste{[inFirstHalfQuadrant(i,3) for i in 1..5]\bound{ifq1b}}
}

10.0.110 Caching Previously Computed Results

⇒ “notitle” (ugUserFreeLocalPage) 10.0.114 on page 2140

```
<ug06.ht>+≡
\begin{page}{ugUserCachePage}{6.12. Caching Previously Computed Results}
\beginscroll
```

By default, Axiom does not save the values of any function. You can cause it to save values and not to recompute unnecessarily by using `\spadcmd{set functions cache}`. This should be used before the functions are defined or, at least, before they are executed. The word following ‘‘cache’’ should be `\axiom{0}` to turn off caching, a positive integer `\axiom{n}` to save the last `\axiom{n}` computed values or ‘‘all’’ to save all computed values. If you then give a list of names of functions, the caching only affects those functions. Use no list of names or ‘‘all’’ when you want to define the default behavior for functions not specifically mentioned in other `\spadcmd{set functions cache}` statements. If you give no list of names, all functions will have the caching behavior. If you explicitly turn on caching for one or more names, you must explicitly turn off caching for those names when you want to stop saving their values.

```
\xctc{
This causes the functions \userfun{f} and \userfun{g} to have
the last three computed values saved.
}{
\spadpaste{set functions cache 3 f g \bound{cache}}
}
\xctc{
This is a sample definition for \userfun{f}.
}{
\spadpaste{f x == factorial(2**x) \bound{fdef}\free{cache}}
}
\xctc{
A message is displayed stating what \userfun{f} will cache.
}{
\spadpaste{f(4) \free{}}\free{cache}}
}
\xctc{
This causes all other functions to have all computed values saved by
default.
}{
\spadpaste{set functions cache all}
}
```

```

\xtc{
This causes all functions that have not been specifically cached in
some way to have no computed values saved.
}{
\spadpaste{}set functions cache 0}
}
\xtc{
We also make \userfun{f} and \userfun{g} uncached.
}{
\spadpaste{}set functions cache 0 f g}
}

\beginImportant
Be careful about caching functions that have \spadglossSee{side
effects}{side effect}. Such a function might destructively modify the
elements of an array or issue a \axiomFun{draw} command, for example.
A function that you expect to execute every time it is called should
not be cached. Also, it is highly unlikely that a function with no
arguments should be cached.
\endImportant

You should also be careful about caching functions that depend on
free variables.
See \downlink{'Free and Local Variables'}{ugUserFreeLocalPage} in
Section 6.16\ignore{ugUserFreeLocal}
for an example.

10.0.111 Recurrence Relations

⇒ “notitle” (ugUserFreeLocalPage) 10.0.114 on page 2140

⇒ “notitle” (ugUserCachePage) 10.0.110 on page 2110

<ug06.ht>+≡

```
\begin{page}{ugUserRecurPage}{6.13. Recurrence Relations}
\beginscroll
```

One of the most useful classes of function are those defined via a
 “recurrence relation.”

A {\it recurrence relation} makes each successive
 value depend on some or all of the previous values.

A simple example is the ordinary “factorial” function:

```
\begin{verbatim}
fact(0) == 1
fact(n | n > 0) == n * fact(n-1)
\end{verbatim}
```

The value of \axiom{fact(10)} depends on the value of \axiom{fact(9)},
 \axiom{fact(9)} on \axiom{fact(8)}, and so on. Because it depends on
 only one previous value, it is usually called a {\it first order
 recurrence relation.} You can easily imagine a function based on two,
 three or more previous values. The Fibonacci numbers are probably the
 most famous function defined by a second order recurrence relation.

```
\xctc{
```

The library function \axiomFun{fibonacci} computes Fibonacci numbers.
 It is obviously optimized for speed.

```
}{
\spadpaste{[fibonacci(i) for i in 0..]}
}
```

```
\xctc{
```

Define the

Fibonacci numbers ourselves using a piece-wise definition.

```
}{
\spadpaste{fib(1) == 1 \bound{fib0}}
}
\xctc{
}{
\spadpaste{fib(2) == 1 \bound{fib1}\free{fib0}}
}
\xctc{
}{
\spadpaste{fib(n) == fib(n-1) + fib(n-2) \bound{fibn}\free{fib1}}
}
```

As defined, this recurrence relation is obviously doubly-recursive. To compute `\axiom{fib(10)}`, we need to compute `\axiom{fib(9)}` and `\axiom{fib(8)}`. And to `\axiom{fib(9)}`, we need to compute `\axiom{fib(8)}` and `\axiom{fib(7)}`. And so on. It seems that to compute `\axiom{fib(10)}` we need to compute `\axiom{fib(9)}` once, `\axiom{fib(8)}` twice, `\axiom{fib(7)}` three times. Look familiar? The number of function calls needed to compute `\axiom{fib(n)}` recurrence relation in the obvious way is exactly `\axiom{fib(n)}`. These numbers grow! For example, if Axiom actually did this, then `\axiom{fib(500)}` requires more than 10^{104} function calls. And, given all this, our definition of `\userfun{fib}` obviously could not be used to calculate the five-hundredth Fibonacci number.

```
\xctc{
Let's try it anyway.
}{
\spadpaste{fib(500) \free{fibn}}
}
```

Since this takes a short time to compute, it obviously didn't do as many as 10^{104} operations! By default, Axiom transforms any recurrence relation it recognizes into an iteration. Iterations are efficient. To compute the value of the `\axiom{n}` term of a recurrence relation using an iteration requires only `\axiom{n}` function calls.¹ If you compare the speed of our `\userfun{fib}` function to the library function, our version is still slower. This is because the library `\axiomFunFrom{fibonacci}{IntegerNumberTheoryFunctions}` uses a 'powering algorithm' with a computing time proportional to $\log^3(n)$ to compute `\axiom{fibonacci(n)}`.

To turn off this special recurrence relation compilation, issue

```
\begin{verbatim}
)set functions recurrence off
\end{verbatim}
```

To turn it back on, substitute '`\tt on`' for '`\tt off`'.

The transformations that Axiom uses for `\userfun{fib}` caches the last two values.² For a more general `\axiom{k}` order recurrence relation, Axiom caches the last `\axiom{k}` values.

If, after computing a value for `\userfun{fib}`, you ask for some larger value, Axiom picks up the cached values and continues computing from there.

See [\downlink{'Free and Local Variables'}{ugUserFreeLocalPage}](#)

in Section 6.16\ignore{ugUserFreeLocal}
 for an example of a function definition that has this same behavior.
 Also see \downlink{‘‘Caching Previously Computed Results’’}
 {ugUserCachePage} in Section 6.12\ignore{ugUserCache}
 for a more general discussion of how you can cache function values.

Recurrence relations can be used for defining recurrence relations
 involving polynomials, rational functions, or anything you like.
 Here we compute the infinite stream of Legendre polynomials.

```
\xctc{
The Legendre polynomial of degree \axiom{0.}
}{
\spadpaste{p(0) == 1\bound{p0}}
}
\xctc{
The Legendre polynomial of degree \axiom{1.}
}{
\spadpaste{p(1) == x\bound{p1}}
}

\xctc{
The Legendre polynomial of degree \axiom{n}.
}{
\spadpaste{p(n) == ((2*n-1)*x*p(n-1) - (n-1)*p(n-2))/n\bound{pn}\free{p1}}
}
\xctc{
Compute the Legendre polynomial of degree \axiom{6.}
}{
\spadpaste{p(6)\free{pn}}
}

10.0.112 Making Functions from Objects

⇒ “notitle” (MakeFunctionXmpPage) 3.76.1 on page 1118

`<ug06.ht>+≡`

```
\begin{page}{ugUserMakePage}{6.14. Making Functions from Objects}
\beginscroll
```

There are many times when you compute a complicated expression and then wish to use that expression as the body of a function. Axiom provides an operation called `\axiomFun{function}` to do this.

It creates a function object and places it into the workspace.

There are several versions, depending on how many arguments the function has.

The first argument to `\axiomFun{function}` is always the expression to be converted into the function body, and the second is always the name to be used for the function.

For more information, see `\downlink{‘MakeFunction’}{MakeFunctionXmpPage}` `\ignore{MakeFunction}`.

```
\xctc{
Start with a simple example of a polynomial in three variables.
}{
\spadpaste{p := -x + y**2 - z**3 \bound{p}}
}
\xctc{
To make this into a function of no arguments that
simply returns the polynomial, use the two argument form of
\axiomFun{function}.
}{
\spadpaste{function(p,'f0) \free{p}\bound{f0}}
}
\xctc{
To avoid possible conflicts (see below), it is a good idea to
quote always this second argument.
}{
\spadpaste{f0 \free{f0}}
}
\xctc{
This is what you get when you evaluate the function.
}{
\spadpaste{f0() \free{f0}}
}
\xctc{
```

To make a function in `\axiom{x}`, use a version of `\axiomFun{function}` that takes three arguments. The last argument is the name of the variable to use as the parameter. Typically, this variable occurs in the expression and, like the function name, you should quote it to avoid possible confusion.

```
{
\spadpaste{function(p,'f1,'x) \free{p}\bound{f1}}
}
\xtc{
This is what the new function looks like.
}{
\spadpaste{f1 \free{f1}}
}
\xtc{
This is the value of \userfun{f1} at \axiom{x = 3}.
Notice that the return type of the function is
\axiomType{Polynomial (Integer)}, the same as \axiom{p}.
}{
\spadpaste{f1(3) \free{f1}}
}
\xtc{
To use \axiom{x} and \axiom{y} as parameters, use the
four argument form of \axiomFun{function}.
}{
\spadpaste{function(p,'f2,'x,'y) \free{p}\bound{f2}}
}
\xtc{
}{
\spadpaste{f2 \free{f2}}
}
\xtc{
Evaluate \axiom{f2} at \axiom{x = 3} and \axiom{y = 0}.
The return type of \userfun{f2} is still
\axiomType{Polynomial(Integer)} because the variable \axiom{z}
is still present and not one of the parameters.
}{
\spadpaste{f2(3,0) \free{f2}}
}
\xtc{
Finally, use all three variables as parameters.
There is no five argument form of \axiomFun{function}, so use the one with
three arguments, the third argument being a list of the parameters.
}{
\spadpaste{function(p,'f3,['x,'y,'z]) \free{p}\bound{f3}}
}
\xtc{
```

Evaluate this using the same values for `\axiom{x}` and `\axiom{y}` as above, but let `\axiom{z}` be `\axiom{-6}`.

The result type of `\userfun{f3}` is `\axiomType{Integer}`.

```
{
\spadpaste{f3 \free{f3}}
}
\xtc{
}{
\spadpaste{f3(3,0,-6) \free{f3}}
}
```

The four functions we have defined via `\axiom{p}` have been undeclared. To declare a function whose body is to be generated by

`\axiomFun{function}`,

issue the declaration `{\it before}` the function is created.

```
\xtc{
}{
\spadpaste{g: (Integer, Integer) -> Float \bound{g}}
}
\xtc{
}{
\spadpaste{D(sin(x-y)/cos(x+y),x) \bound{prev}}
}
\xtc{
}{
\spadpaste{function(\%, 'g, 'x, 'y) \free{g} \free{prev}}
}
\xtc{
}{
\spadpaste{g \free{g}}
}
```

It is an error to use `\axiom{g}` without the quote in the penultimate expression since `\axiom{g}` had been declared but did not have a value. Similarly, since it is common to overuse variable names like `\axiom{x}`, `\axiom{y}`, and so on, you avoid problems if you always quote the variable names for `\axiomFun{function}`. In general, if `\axiom{x}` has a value and you use `\axiom{x}` without a quote in a call to `\axiomFun{function}`, then Axiom does not know what you are trying to do.

What kind of object is allowable as the first argument to `\axiomFun{function}`? Let's use the `\Browse{}` facility of Hyperdoc to find out. At the main `\Browse{}` menu, enter the string `{\tt function}` and then click on `{\bf Operations.}` The exposed operations called `\axiomFun{function}` all take an object whose type belongs to category `\axiomType{ConvertibleTo InputForm}`. What domains are those? Go back

to the main \Browse{} menu, erase {\tt function}, enter {\tt ConvertibleTo} in the input area, and click on {\bf categories} on the {\bf Constructors} line. At the bottom of the page, enter {\tt InputForm} in the input area following {\bf S =}. Click on {\bf Cross Reference} and then on {\bf Domains}. The list you see contains over forty domains that belong to the category \axiomType{ConvertibleTo InputForm}. Thus you can use \axiomFun{function} for \axiomType{Integer}, \axiomType{Float}, \axiomType{Symbol}, \axiomType{Complex}, \axiomType{Expression}, and so on.

10.0.113 Functions Defined with Blocks

⇒ “notitle” (ugLangBlocksPage) 9.0.76 on page 1961

```
<ug06.ht>+≡
\begin{page}{ugUserBlocksPage}{6.15. Functions Defined with Blocks}
\beginscroll
```

You need not restrict yourself to functions that only fit on one line or are written in a piece-wise manner.

The body of the function can be a block, as discussed in

```
\downlink{‘‘Blocks’’}{ugLangBlocksPage}
in Section 5.2\ignore{ugLangBlocks}.
```

```
\labelSpace{1pc}
\xtc{
Here is a short function that swaps two elements of a list,
array or vector.
}{
\begin{spadsrc}[\bound{swap}]
swap(m,i,j) ==
    temp := m.i
    m.i := m.j
    m.j := temp
\end{spadsrc}
}
\xtc{
The significance of \userfun{swap} is that it has a destructive
effect on its first argument.
}{
\spadpaste{k := [1,2,3,4,5] \bound{k}}
}
\xtc{
}{
\spadpaste{swap(k,2,4) \free{1 swap}\bound{swapk}}
}
\xtc{
You see that the second and fourth elements are interchanged.
}{
\spadpaste{k \free{swapk}}
}

\xtc{
Using this, we write a couple of different sort functions.
First, a simple bubble sort.
```

The operation `\axiomOpFrom{\#}{List}` returns the number of elements in an aggregate.

```
{
\begin{spadsrc}[\bound{bubbleSort}]
bubbleSort(m) ==
  n := #m
  for i in 1..(n-1) repeat
    for j in n..(i+1) by -1 repeat
      if m.j < m.(j-1) then swap(m,j,j-1)
  m
\end{spadsrc}
}

\xtc{
Let this be the list we want to sort.
}{
\spadpaste{m := [8,4,-3,9] \bound{m}}
}

\xtc{
This is the result of sorting.
}{
\spadpaste{bubbleSort(m) \free{m swap bubbleSort}\bound{sortm}}
}

\xtc{
Moreover, \axiom{m} is destructively changed to be the sorted version.
}{
\spadpaste{m \free{sortm}}
}

\xtc{
This function implements an insertion sort.
The basic idea is to traverse the list and insert the \eth{\axiom{i}}
element in its correct position among the \axiom{i-1} previous
elements.
Since we start at the beginning of the list, the list elements before the
\eth{\axiom{i}} element have already been placed in ascending order.
}{
\begin{spadsrc}[\bound{insertionSort}]
insertionSort(m) ==
  for i in 2..#m repeat
    j := i
    while j > 1 and m.j < m.(j-1) repeat
      swap(m,j,j-1)
      j := j - 1
  m
\end{spadsrc}
}
```

```

\xtc{
As with our bubble sort, this is a destructive function.
}{
\spadpaste{m := [8,4,-3,9] \bound{m1}}
}
\xtc{
}{
\spadpaste{insertionSort(m) \free{m1 swap insertionSort}\bound{sortm1}}
}
\xtc{
}{
\spadpaste{m \free{sortm1}}
}

```

Neither of the above functions is efficient for sorting large lists since they reference elements by asking for the `\eth{\axiom{j}}` element of the structure `\axiom{m}`.

```

\xtc{
Here is a more efficient bubble sort for lists.
}{
\begin{spadsrc}[\bound{bubbleSort2}]
bubbleSort2(m: List Integer): List Integer ==
  null m => m
  l := m
  while not null (r := l.rest) repeat
    r := bubbleSort2 r
    x := l.first
    if x < r.first then
      l.first := r.first
      r.first := x
    l.rest := r
  l := l.rest
  m
\end{spadsrc}
}
\xtc{
Try it out.
}{
\spadpaste{bubbleSort2 [3,7,2]\free{bubbleSort2}}
}

```

This definition is both recursive and iterative, and is tricky! Unless you are `{\it really}` curious about this definition, we suggest you skip immediately to the next section.

Here are the key points in the definition. First notice that if you are sorting a list with less than two elements, there is nothing to do: just return the list. This definition returns immediately if there are zero elements, and skips the entire `\axiom{while}` loop if there is just one element.

The second point to realize is that on each outer iteration, the bubble sort ensures that the minimum element is propagated leftmost. Each iteration of the `\axiom{while}` loop calls `\userfun{bubbleSort2}` recursively to sort all but the first element. When finished, the minimum element is either in the first or second position. The conditional expression ensures that it comes first. If it is in the second, then a swap occurs. In any case, the `\axiomFun{rest}` of the original list must be updated to hold the result of the recursive call.

<ug06.ht>+≡

```
\begin{page}{ugUserFreeLocalPage}{6.16. Free and Local Variables}
\beginscroll
```

When you want to refer to a variable that is not local to your function, use a ‘‘\axiom{free}’’ declaration. \spadkey{free} Variables declared to be \axiom{free} are assumed to be defined globally in the workspace.

```
\labelSpace{1pc}
\xtc{
This is a global workspace variable.
}{
\spadpaste{counter := 0 \bound{counter}}
}
\xtc{
This function refers to the global \axiom{counter}.
}{
\begin{spadsrc}[\free{counter}\bound{f}]
f() ==
    free counter
    counter := counter + 1
\end{spadsrc}
}
\xtc{
The global \axiom{counter} is incremented by \axiom{1}.
}{
\spadpaste{f() \free{f}\bound{f1}}
}
\xtc{
}{
\spadpaste{counter \free{f1}}
}
```

Usually Axiom can tell that you mean to refer to a global variable and so \axiom{free} isn’t always necessary. However, for clarity and the sake of self-documentation, we encourage you to use it.

Declare a variable to be ‘‘\axiom{local}’’ when you do not want to refer to

a global variable by the same name.

```
\xctc{
This function uses \axiom{counter} as a local variable.
}{
\begin{spadsrc}[\bound{g}]
g() ==
  local counter
  counter := 7
\end{spadsrc}
}
\xctc{
Apply the function.
}{
\spadpaste{g() \free{g}}
}
\xctc{
Check that the global value of \axiom{counter} is unchanged.
}{
\spadpaste{counter\free{g f1}}
}
```

Parameters to a function are local variables in the function. Even if you issue a `\axiom{free}` declaration for a parameter, it is still local.

What happens if you do not declare that a variable `\axiom{x}` in the body of your function is `\axiom{local}` or `\axiom{free}`? Well, Axiom decides on this basis:

```
\indent{4}
\beginitems
\item[1. ] Axiom scans your function line-by-line, from top-to-bottom.
The right-hand side of an assignment is looked at before the left-hand
side.
\item[2. ] If \axiom{x} is referenced before it is assigned a value,
it is a \axiom{free} (global) variable.
\item[3. ] If \axiom{x} is assigned a value before it is referenced,
it is a \axiom{local} variable.
\enditems
\indent{0}

\xctc{
Set two global variables to 1.
}{
\spadpaste{a := b := 1\bound{ab1}}
```

```

}
\xtc{
Refer to \axiom{a} before it is assigned a value, but
assign a value to \axiom{b} before it is referenced.
}{
\begin{spadsrc}[\bound{hh}]
h() ==
  b := a + 1
  a := b + a
\end{spadsrc}
}
\xtc{
Can you predict this result?
}{
\spadpaste{h() \free{ab1 hh}\bound{hhh}}
}
\xtc{
How about this one?
}{
\spadpaste{[a, b] \free{hhh}}
}

```

What happened? In the first line of the function body for `\axiom{h}`, `\axiom{a}` is referenced on the right-hand side of the assignment. Thus `\axiom{a}` is a free variable. The variable `\axiom{b}` is not referenced in that line, but it is assigned a value. Thus `\axiom{b}` is a local variable and is given the value `\axiom{a + 1 = 2}`. In the second line, the free variable `\axiom{a}` is assigned the value `\axiom{b + a}` which equals `\axiom{2 + 1 = 3}`. This is the value returned by the function. Since `\axiom{a}` was free in `\userfun{h}`, the global variable `\axiom{a}` has value `\axiom{3}`. Since `\axiom{b}` was local in `\userfun{h}`, the global variable `\axiom{b}` is unchanged---it still has the value `\axiom{1}`.

It is good programming practice always to declare global variables. However, by far the most common situation is to have local variables in your functions. No declaration is needed for this situation, but be sure to initialize their values.

Be careful if you use free variables and you cache the value of your function (see `\downlink{''Caching Previously Computed Results''}` `{ugUserCachePage}` in Section 6.12 `\ignore{ugUserCache}`). Caching `{\it only}` checks if the values of the function arguments are the same as in a function call previously seen. It does not check if any of the free variables on which the function depends have changed between function calls.

```

\xtc{
Turn on caching for \userfun{p}.
}{
\spadpaste{)set fun cache all p \bound{pcache}}
}
\xtc{
Define \userfun{p} to depend on the free variable \axiom{N}.
}{
\spadpaste{p(i,x) == ( free N;
reduce( + , [ (x-i)**n for n in 1..N ] ) ) \free{pcache}\bound{pdef}}
}
\xtc{
Set the value of \axiom{N}.
}{
\spadpaste{N := 1 \bound{Nass}}
}
\xtc{
Evaluate \userfun{p} the first time.
}{
\spadpaste{p(0, x) \free{pdef Nass}\bound{pfirst}}
}
\xtc{
Change the value of \axiom{N}.
}{
\spadpaste{N := 2 \bound{Nass2}}
}
\xtc{
Evaluate \userfun{p} the second time.
}{
\spadpaste{p(0, x) \free{pfirst Nass2}}
}
If caching had been turned off, the second evaluation would have
reflected the changed value of \axiom{N}.
\xtc{
Turn off caching for \userfun{p}.
}{
\spadpaste{)set fun cache 0 p}
}

```

Axiom does not allow {\it fluid variables}, that is, variables \spadglossSee{bound}{binding} by a function \spad{f} that can be referenced by functions called by \spad{f}.

Values are passed to functions by \spadgloss{reference}: a pointer to the value is passed rather than a copy of the value or a pointer to a copy.

```

\xtc{
This is a global variable that is bound to a record object.
}{
\spadpaste{r : Record(i : Integer) := [1] \free{r}}
}
\xtc{
This function first modifies the one component of its
record argument and then rebinds the parameter to another
record.
}{
\begin{spadsrc}[\bound{resetRecord}]
resetRecord rr ==
    rr.i := 2
    rr := [10]
\end{spadsrc}
}
\xtc{
Pass \axiom{r} as an argument to \userfun{resetRecord}.
}{
\spadpaste{resetRecord r \free{r resetRecord}\bound{rr}}
}
\xtc{
The value of \axiom{r} was changed by the expression
\axiom{rr.i := 2} but not by \axiom{rr := [10]}.
}{
\spadpaste{r \free{rr}}
}

```

To conclude this section, we give an iterative definition of a function that computes Fibonacci numbers. This definition approximates the definition into which Axiom transforms the recurrence relation definition of `\userfun{fib}` in `\downlink{'Recurrence Relations'}{ugUserRecurPage}` in Section 6.13\ignore{ugUserRecur}.

```

\xtc{
Global variables
\axiom{past} and \axiom{present} are used
to hold the last computed Fibonacci numbers.
}{
\spadpaste{past := present := 1\bound{f0}}
}
\xtc{
Global variable \axiom{index} gives the
current index of \axiom{present}.

```

```

}{
\spadpaste{index := 2\bound{f1}\free{f0}}
}
\xtc{
Here is a recurrence relation defined in terms
of these three global variables.
}{
\begin{spadsrc}[\bound{f3}\free{f2}]
fib(n) ==
  free past, present, index
  n < 3 => 1
  n = index - 1 => past
  if n < index-1 then
    (past,present) := (1,1)
    index := 2
  while (index < n) repeat
    (past,present) := (present, past+present)
    index := index + 1
  present
\end{spadsrc}
}
\xtc{
Compute the infinite stream of Fibonacci numbers.
}{
\spadpaste{fibs := [fib(n) for n in 1..] \bound{fibs}\free{f3}}
}
\xtc{
What is the 1000th Fibonacci number?
}{
\spadpaste{fibs 1000 \free{fibs}}
}

```

As an exercise, we suggest you write a function in an iterative style that computes the value of the recurrence relation

$p(n) = p(n-1) - 2 \cdot p(n-2) + 4 \cdot p(n-3)$

$\{\text{axiom}\{p(n) = p(n-1) - 2 \cdot p(n-2) + 4 \cdot p(n-3)\}\}$

having the initial values

$p(1) = 1, p(2) = 3$ and $p(3) = 9$.

$\{\text{axiom}\{p(1) = 1, p(2) = 3 \text{ and } p(3) = 9.\}\}$

How would you write the function using an element

`\axiomType{OneDimensionalArray}` or `\axiomType{Vector}`

to hold the previously computed values?

```

```
\beginImportant
```

An {\it anonymous function} is a function that is defined

by giving a list of parameters, the ‘‘maps-to’’ compound symbol `\axiomSyntax{+>}` `\texht{(from the mathematical symbol \mapsto)}`, and by an expression involving the parameters, the evaluation of which determines the return value of the function.

and by an expression involving the parameters, the evaluation of which determines the return value of the function.

```
\centerline{{{ \tt ( \subscriptIt{parm}{1}, \subscriptIt{parm}{2},
\ldots, \subscriptIt{parm}{N} ) +> {\it expression}}}}
\endImportant
```

You can apply an anonymous function in several ways.

```
\indent{4}
```

```
\beginitems
```

\item[1.] Place the anonymous function definition in parentheses directly followed by a list of arguments.

\item[2.] Assign the anonymous function to a variable and then use the variable name when you would normally use a function name.

\item[3.] Use `\axiomSyntax{==}` to use the anonymous function definition as the arguments and body of a regular function definition.

\item[4.] Have a named function contain a declared anonymous function and use the result returned by the named function.

10.0.116 Some Examples

<ug06.ht>+≡

```
\begin{page}{ugUserAnonExampPage}{6.17.1. Some Examples}
\beginscroll
```

Anonymous functions are particularly useful for defining functions ‘‘on the fly.’’ That is, they are handy for simple functions that are used only in one place.

In the following examples, we show how to write some simple anonymous functions.

```
\xtc{
This is a simple absolute value function.
}{
\spadpaste{x +-> if x < 0 then -x else x \bound{anon0}}
}
\xtc{
}{
\spadpaste{abs1 := \% \free{anon0}\bound{abs1}}
}
\xtc{
This function returns {\tt true} if the absolute value of
the first argument is greater than the absolute value of the
second, {\tt false} otherwise.
}{
\spadpaste{(x,y) +-> abs1(x) > abs1(y) \bound{anon1}\free{abs1}}
}
\xtc{
We use the above function to ‘‘sort’’ a list of integers.
}{
\spadpaste{sort(\%, [3,9,-4,10,-3,-1,-9,5]) \free{anon1}}
}

\xtc{
This function returns \axiom{1} if \axiom{i + j} is even,
\axiom{-1} otherwise.
}{
\spadpaste{ev := ( (i,j) +-> if even?(i+j) then 1 else -1) \bound{ev}}
}
\xtc{
We create a four-by-four matrix containing \axiom{1} or \axiom{-1}
depending on whether the row plus the column index is even or not.
}{
\spadpaste{matrix([[ev(row,col) for row in 1..4] for col in 1..4]) \free{ev}}
}
```

```

\xtc{
This function returns {\tt true} if a polynomial in \axiom{x} has multiple
roots, {\tt false} otherwise.
It is defined and applied in the same expression.
}{
\spadpaste{( p +-> not one?(gcd(p,D(p,x))) )(x**2+4*x+4)}
}

\xtc{
This and the next expression are equivalent.
}{
\spadpaste{g(x,y,z) == cos(x + sin(y + tan(z)))}
}
\xtc{
The one you use is a matter of taste.
}{
\spadpaste{g == (x,y,z) +-> cos(x + sin(y + tan(z)))}
}

\endscroll

10.0.117 Declaring Anonymous Functions

```

<ug06.ht>+≡
\begin{page}{ugUserAnonDeclarePage}{6.17.2. Declaring Anonymous Functions}
\beginscroll

```

If you declare any of the arguments you must declare all of them.

Thus,

```

\begin{verbatim}
(x: INT,y): FRAC INT +-> (x + 2*y)/(y - 1)
\end{verbatim}
is not legal.

```

```

\xtc{
This is an example of a fully declared anonymous
function.
The output shown just indicates that the object you created is a
particular kind of map, that is, function.
}{

```

```

\spadpaste{(x: INT,y: INT): FRAC INT +-> (x + 2*y)/(y - 1)}
}

```

```

\xtc{
Axiom allows you to declare the arguments and not declare
the return type.
}{

```

```

\spadpaste{(x: INT,y: INT) +-> (x + 2*y)/(y - 1)}
}

```

The return type is computed from the types of the arguments and the body of the function.

You cannot declare the return type if you do not declare the arguments.

Therefore,

```

\begin{verbatim}
(x,y): FRAC INT +-> (x + 2*y)/(y - 1)
\end{verbatim}
is not legal.

```

```

\xtc{
This and the next expression are equivalent.
}{

```

```

\spadpaste{h(x: INT,y: INT): FRAC INT == (x + 2*y)/(y - 1)}
}

```

```

\xtc{
The one you use is a matter of taste.
}{

```

```

\spadpaste{h == (x: INT,y: INT): FRAC INT +-> (x + 2*y)/(y - 1)}
}

```

When should you declare an anonymous function?

```
\indent{4}
\beginitems
\item[1. ] If you use an anonymous function and Axiom can't figure
out what you are trying to do, declare the function.
\item[2. ] If the function has nontrivial argument types or a
nontrivial return type that
Axiom may be able to determine eventually, but you are not
willing to wait that long, declare the function.
\item[3. ] If the function will only be used for arguments of specific
types and it is not too much trouble to declare the function, do so.
\item[4. ] If you are using the anonymous function as an argument to
another function (such as \axiomFun{map} or \axiomFun{sort}),
consider declaring the function.
\item[5. ] If you define an anonymous function inside a named function,
you {\it must} declare the anonymous function.
\enditems
\indent{0}
```

```
\xctc{
This is an example of a named function for integers that returns a
function.
}{
\spadpaste{addx x == ((y: Integer): Integer +-> x + y) \bound{addx}}
}
\xctc{
We define \userfun{g} to be a function that adds \axiom{10} to its
argument.
}{

}
}
```

An anonymous function cannot be recursive: since it does not have a name, you cannot even call it within itself!

If you place an anonymous function inside a named function, the anonymous function must be declared.

10.0.118 Example: A Database

<ug06.ht>+≡

```
\begin{page}{ugUserDatabasePage}{6.18. Example: A Database}
\beginscroll
```

This example shows how you can use Axiom to organize a database of lineage data and then query the database for relationships.

```
\labelSpace{1.5pc}
\xtc{
The database is entered as ‘‘assertions’’ that are really
pieces of a function definition.
}{
\spadpaste{children("albert") == ["albertJr","richard","diane"]\bound{d1}}
}
\xtc{
Each piece
\axiom{children(x) == y} means
‘‘the children of \axiom{x} are \axiom{y}’’.
}{
\spadpaste{children("richard") == ["douglas","daniel","susan"]}
\free{d1}\bound{d2}}
}
\xtc{
This family tree thus spans four generations.
}{
\spadpaste{children("douglas") == ["dougie","valerie"]\free{d2}\bound{d3}}
}
\xtc{
Say ‘‘no one else has children.’’
}{
\spadpaste{children(x) == []\free{d3}\bound{d4}}
}

\xtc{
We need some functions for computing lineage.
Start with \axiom{childOf}.
}{
\spadpaste{childOf(x,y) == member?(x,children(y))\bound{d9}\free{d10}}
}
\xtc{
To find the \axiom{parentOf} someone,
you have to scan the database of
people applying \axiom{children}.
}{
```

```

\begin{spadsrc}[\bound{d8a}\free{d9}]
parentOf(x) ==
  for y in people repeat
    (if childOf(x,y) then return y)
  "unknown"
\end{spadsrc}
}
\xtc{
And a grandparent of \axiom{x} is just a parent of a parent of \axiom{x}.
}{
\spadpaste{grandParentOf(x) == parentOf parentOf x\bound{d8}\free{d8a}}
}
\xtc{
The grandchildren of \axiom{x}
are the people \axiom{y} such that
\axiom{x} is a grandparent of \axiom{y}.
}{
\spadpaste{grandchildren(x) == [y for y in people | grandParentOf(y) = x]
\free{d7}\bound{d8}}
}
\xtc{
Suppose you want to make a list of all great-grandparents.
Well, a great-grandparent is a grandparent of a person who has children.
}{
\begin{spadsrc}[\free{d6}\bound{d7}]
greatGrandParents == [x for x in people |
  reduce(_or,[not empty? children(y) for y in grandchildren(x)],false)]
\end{spadsrc}
}
\xtc{
Define \axiom{descendants} to include the parent as well.
}{
\begin{spadsrc}[\free{d5}\bound{d6}]
descendants(x) ==
  kids := children(x)
  null kids => [x]
  concat(x,reduce(concat,[descendants(y)
    for y in kids],[ ]))
\end{spadsrc}
}
\xtc{
Finally, we need a list of people.
Since all people are descendants of ‘‘albert’’, let’s say so.
}{
\spadpaste{people == descendants "albert"\free{d4}\bound{d5}}
}

```

We have used `\axiomSyntax{==}` to define the database and some functions to query the database.

But no computation is done until we ask for some information.

Then, once and for all, the functions are analyzed and compiled to machine code for run-time efficiency.

Notice that no types are given anywhere in this example.

They are not needed.

```
\xrc{
Who are the grandchildren of ‘‘richard’’?
}{
\spadpaste{grandchildren "richard"\bound{d10}\free{d11}}
}
\xrc{
Who are the great-grandparents?
}{
\spadpaste{greatGrandParents\bound{d11}\free{d12}}
}
```

```

10.0.119 Example: A Famous Triangle

⇒ “notitle” (ugTypesExposePage) 7.0.54 on page 1896

```
<ug06.ht>+≡
\begin{page}{ugUserTrianglePage}{6.19. Example: A Famous Triangle}
\beginscroll
```

In this example we write some functions that display
Pascal’s triangle.

It demonstrates the use of piece-wise definitions and some output
operations you probably haven’t seen before.

```
\labelSpace{1pc}
\xtc{
To make these output operations
available, we have to \spadgloss{expose} the domain
\axiomType{OutputForm}.
See \downlink{‘‘Exposing Domains and Packages’’}{ugTypesExposePage}
in Section 2.11\ignore{ugTypesExpose} for
more information about exposing domains
and packages.
}{
\spadpaste{)set expose add constructor OutputForm \bound{expose}}
}
\xtc{
Define the values along the first
row and any column \axiom{i}.
}{
\spadpaste{pascal(1,i) == 1 \bound{pas1}}
}
\xtc{
Define the values for when the row
and column index \axiom{i} are equal.
Repeating the argument name indicates that
the two index values are equal.
}{
\spadpaste{pascal(n,n) == 1 \bound{pas2}\free{pas1}}
}
\xtc{
}{
\begin{spadsrc}[\bound{pas3}\free{pas1 pas2}]
pascal(i,j | 1 < i and i < j) ==
    pascal(i-1,j-1)+pascal(i,j-1)
\end{spadsrc}
```

```

}
Now that we have defined the coefficients in Pascal's triangle,
let's write a couple of one-liners to display it.
\xtc{
First, define a function that gives the \eth{\axiom{n}} row.
}{
\spadpaste{pascalRow(n) == [pascal(i,n) for i in 1..n]
\bound{pascalRow}\free{pas3}}
}
\xtc{
Next, we write the function \userfun{displayRow}
to display the row, separating entries by blanks and centering.
}{
\spadpaste{displayRow(n) == output center blankSeparate pascalRow(n)
\free{pascalRow}\bound{displayRow}\free{expose}}
}
%
Here we have used three output operations.
Operation \axiomFunFrom{output}{OutputForm}
displays the printable form of objects on the screen,
\axiomFunFrom{center}{OutputForm} centers a printable form in the
width of the screen, and \axiomFunFrom{blankSeparate}{OutputForm}
takes a list of printable forms and inserts a blank between
successive elements.
\xtc{
Look at the result.
}{
\spadpaste{for i in 1..7 repeat displayRow i \free{displayRow}}
}
Being purists, we find this less than satisfactory.
Traditionally, elements of Pascal's triangle are centered between
the left and right elements on the line above.
%
\xtc{
To fix this misalignment, we go back and
redefine \userfun{pascalRow} to right adjust the entries within the
triangle within a width of four characters.
}{
\spadpaste{pascalRow(n) == [right(pascal(i,n),4) for i in 1..n]
\bound{pascalRow2}}
}
%
\xtc{
Finally let's look at our purely reformatted triangle.
}{
\spadpaste{for i in 1..7 repeat displayRow i \free{pascalRow2}}
}

```

```

\free{displayRow}}
}
\xtc{
Unexpose \axiomType{OutputForm} so we don't get unexpected
results later.
}{
\spadpaste{)set expose drop constructor OutputForm}
}

\endscroll

10.0.120 Example: Testing for Palindromes

⇒ “notitle” (ugUserTrianglePage) 10.0.119 on page 2177

```
<ug06.ht>+≡
\begin{page}{ugUserPalPage}{6.20. Example: Testing for Palindromes}
\beginscroll
```

In this section we define a function `\userfun{pal?}` that tests whether its argument is a `{\it palindrome}`, that is, something that reads the same backwards and forwards. For example, the string ‘‘Madam I’m Adam’’ is a palindrome (excluding blanks and punctuation) and so is the number `\axiom{123454321.}` The definition works for any datatype that has `\axiom{n}` components that are accessed by the indices `\axiom{1\ldots n}`.

```
\xctc{
Here is the definition for \userfun{pal?}.
It is simply a call to an auxiliary function called
\userfun{palAux?}.
We are following the convention of ending a function’s name with
\axiomSyntax{?} if the function returns a \axiomType{Boolean} value.
}{
\spadpaste{pal? s == palAux?(s,1,\#s) \bound{pal}}
}
\xctc{
Here is \userfun{palAux?}.
It works by comparing elements that are equidistant from the start and end
of the object.
}{
\begin{spadsrc}[\bound{palAux}]
palAux?(s,i,j) ==
  j > i =>
    (s.i = s.j) and palAux?(s,i+1,i-1)
  true
\end{spadsrc}
}
\xctc{
Try \userfun{pal?} on some examples.
First, a string.
}{
\spadpaste{pal? "Oxford" \free{pal palAux}}
}
\xctc{
```

```

10.0.121 Rules and Pattern Matching

<ug06.ht>+≡

```
\begin{page}{ugUserRulesPage}{6.21. Rules and Pattern Matching}
\beginscroll
```

A common mathematical formula is

```
\texht{\narrowDisplay{%
\log(x) + \log(y) = \log(x y) \quad\forall \, x \hbox{\, and \, } y.}}{
\axiom{\log(x) + \log(y) == \log(x * y)} for any \axiom{x} and \axiom{y}.}
```

The presence of

```
\texht{‘‘$\forall$’’}{the word ‘‘any’’}
indicates that \axiom{x} and \axiom{y} can stand for arbitrary mathematical
expressions in the above formula.
```

You can use such mathematical formulas in Axiom to specify ‘‘rewrite rules’’.

Rewrite rules are objects in Axiom that can be assigned to variables for later use, often for the purpose of simplification.

Rewrite rules look like ordinary function definitions except that they are preceded by the reserved word `\axiom{rule}`.

```
\spadkey{rule}
```

For example, a rewrite rule for the above formula is:

```
\begin{verbatim}
rule log(x) + log(y) == log(x * y)
\end{verbatim}
```

Like function definitions, no action is taken when a rewrite rule is issued.

Think of rewrite rules as functions that take one argument.

When a rewrite rule `\axiom{A = B}` is applied to an argument `\axiom{f}`, its meaning is: ‘‘rewrite every subexpression of `\axiom{f}` that *{it matches}* `\axiom{A}` by `\axiom{B}`.’’

The left-hand side of a rewrite rule is called a `\spadgloss{pattern}`; its right-side side is called its `\spadgloss{substitution}`.

```
\xtc{
```

Create a rewrite rule named `\userfun{logrule}`.

The generated symbol beginning with a `\axiomSyntax{\%}` is a place-holder for any other terms that might occur in the sum.

```
}{
\spadpaste{logrule := rule log(x) + log(y) == log(x * y) \bound{logrule}}
}
```

```
\xtc{
```

Create an expression with logarithms.

```
}{
\spadpaste{f := log sin x + log x \bound{f}}
}
```

```
\xtc{
```

```

Apply \userfun{logrule} to \axiom{f}.
}{
\spadpaste{logrule f \free{f}\free{logrule}}
}

```

The meaning of our example rewrite rule is:

“for all expressions $\text{\axiom{x}}$ and $\text{\axiom{y}}$, rewrite $\text{\axiom{log(x) + log(y)}}$ by $\text{\axiom{log(x * y)}}$.”

Patterns generally have both operation names

(here, $\text{\axiomFun{log}}$ and $\text{\axiomOp{+}}$)

and variables (here, $\text{\axiom{x}}$ and $\text{\axiom{y}}$).

By default, every operation name stands for itself.

Thus $\text{\axiomFun{log}}$ matches only “ $\text{\axiom{log}}$ ” and not any other operation such as $\text{\axiomFun{sin}}$.

On the other hand, variables do not stand for themselves.

Rather, a variable denotes a

$\{\text{it pattern variable}\}$ that is free to match any expression whatsoever.

When a rewrite rule is applied, a process called $\text{\spadgloss{pattern matching}}$ goes to work by systematically scanning the subexpressions of the argument. When a subexpression is found that “matches” the pattern, the subexpression is replaced by the right-hand side of the rule. The details of what happens will be covered later.

The customary Axiom notation for patterns is actually a shorthand for a longer, more general notation. Pattern variables can be made explicit by using a percent ($\text{\axiomSyntax{\%}}$) as the first character of the variable name. To say that a name stands for itself, you can prefix that name with a quote operator ($\text{\axiomSyntax{'}}$). Although the current Axiom parser does not let you quote an operation name, this more general notation gives you an alternate way of giving the same rewrite rule:

```

\begin{verbatim}
rule log(%x) + log(%y) == log(x * y)
\end{verbatim}

```

This longer notation gives you patterns that the standard notation won't handle.

For example, the rule

```

\texht{\typeout{check this example}}{}
\begin{verbatim}
rule %f(c * 'x) == c*f(x)
\end{verbatim}

```

means “for all $\text{\axiom{f}}$ and $\text{\axiom{c}}$, replace $\text{\axiom{f(y)}}$ by $\text{\axiom{c * f(x)}}$ when $\text{\axiom{y}}$ is the product of $\text{\axiom{c}}$ and the explicit variable $\text{\axiom{x}}$.”

```
\beginImportant
To enter a single rule in Axiom, use the following syntax:
\spadkey{rule}
\centerline{{{\\tt rule {\it leftHandSide} == {\it rightHandSide}}}}
The {\it leftHandSide} is a pattern to be matched and
the {\it rightHandSide} is its substitution.
The rule is an object of type \axiomType{RewriteRule} that can be
assigned to a variable and applied to expressions to transform them.
\endImportant
```

```
\xtc{
Create a ruleset named \axiom{logrules}.
}{
\begin{spadsrc}[\bound{logrules}]
logrules := rule
  log(x) + log(y) == log(x * y)
  y * log x      == log(x ** y)
\end{spadsrc}
}
\xtc{
Again, create an expression \axiom{f} containing logarithms.
}{
\spadpaste{f := a * log(sin x) - 2 * log x \bound{f1}}
}
\xtc{
Apply the ruleset \userfun{logrules} to \axiom{f}.
}{
\spadpaste{logrules f \free{f1}\free{logrules}}
}
}
```

We have allowed pattern variables to match arbitrary expressions in the above examples. Often you want a variable only to match expressions satisfying some predicate. For example, we may want to apply the transformation $\text{\texttt{\textbackslash texht{\narrowDisplay{y \log(x) = \log(x^y)}}}}$ only when $\text{\texttt{\textbackslash axiom{y}}}$ is an integer.

The way to restrict a pattern variable $\text{\texttt{\textbackslash axiom{y}}}$ by a predicate $\text{\texttt{\textbackslash axiom{f(y)}}}$ is by using a vertical bar $\text{\texttt{\textbackslash axiomSyntax{}}}$, which means ‘‘such that,’’ in much the same way it is used in function definitions. You do this only once, but at the earliest (meaning deepest and leftmost) part of the pattern.

```
\xrc{
This restricts the logarithmic rule to create integer exponents only.
}{
```

```
\begin{spadsrc}[\bound{logrules2}]
logrules2 := rule
  log(x) + log(y)          == log(x * y)
  (y | integer? y) * log x == log(x ** y)
\end{spadsrc}
}
```

```
\xrc{
Compare this with the result of applying the previous set of rules.
}{
```

```
\spadpaste{f \free{f1}}
}
\xrc{
}{
\spadpaste{logrules2 f \free{f1}\free{logrules2}}
}
```

You should be aware that you might need to apply a function like $\text{\texttt{\textbackslash spadfun{integer}}}$ within your predicate expression to actually apply the test function.

```
\xrc{
Here we use \spadfun{integer} because \spad{n} has
type \spadtype{Expression Integer} but \spadfun{even?} is an operation
defined on integers.
}{
```

```
\spadpaste{
evenRule := rule cos(x)**(n | integer? n and even? integer n)==
(1-sin(x)**2)**(n/2) \bound{evenRule}}
}
```

```
\xrc{
Here is the application of the rule.
}{
\spadpaste{evenRule( cos(x)**2 ) \free{evenRule}}
```

```

}
\xtc{
This is an example of some of the usual identities involving products of
sines and cosines.
}{
\begin{spadsrc}[\bound{sinCosProducts}]
sinCosProducts == rule
  sin(x) * sin(y) == (cos(x-y) - cos(x + y))/2
  cos(x) * cos(y) == (cos(x-y) + cos(x+y))/2
  sin(x) * cos(y) == (sin(x-y) + sin(x + y))/2
\end{spadsrc}
}

}
\xtc{
}{
\spadpaste{sinCosProducts g \free{sinCosProducts g}}
}

```

Another qualification you will often want to use is to allow a pattern to match an identity element. Using the pattern `\axiom{x + y}`, for example, neither `\axiom{x}` nor `\axiom{y}` matches the expression `\axiom{0}`. Similarly, if a pattern contains a product `\axiom{x*y}` or an exponentiation `\axiom{x**y}`, then neither `\axiom{x}` or `\axiom{y}` matches `\axiom{1}`.

```

\xtc{
If identical elements were matched, pattern matching would generally loop.
Here is an expansion rule for exponentials.
}{
\spadpaste{exprule := rule exp(a + b) == exp(a) * exp(b)\bound{exprule}}
}
\xtc{
This rule would cause infinite rewriting on this if either \axiom{a} or
\axiom{b} were allowed to match \axiom{0}.
}{
\spadpaste{exprule exp x \free{exprule}}
}

```

There are occasions when you do want a pattern variable in a sum or product to match `\axiom{0}` or `\axiom{1}`. If so, prefix its name with a `\axiomSyntax{?}` whenever it appears in a left-hand side of a rule. For example, consider the following rule for the exponential integral:

`\texht{\narrowDisplay{\int \left(\frac{y+e^x}{x}\right)\!:\! dx = \int \frac{y}{x}\!:\! dx + \hbox{\rm Ei}(x) \quad\forall\, x \hbox{\rm and}\, y.}}{\axiom{integral((y + exp x)/x, x) == integral(y/x, x) + Ei x} for any \axiom{x} and \axiom{y}.}` This rule is valid for `\axiom{y = 0}`. One solution is to create a `\axiomType{Ruleset}` with two rules, one with and one without `\axiom{y}`. A better solution is to use an “optional” pattern variable.

```
\xctc{
Define rule \axiom{eirule} with
a pattern variable \axiom{?y} to indicate
that an expression may or may not occur.
}{
\spadpaste{eirule := rule integral((?y + exp x)/x,x) ==
integral(y/x,x) + Ei x \bound{eirule}}
}
\xctc{
Apply rule \axiom{eirule} to an integral without this term.
}{
\spadpaste{eirule integral(exp u/u, u) \free{eirule}}
}
\xctc{
Apply rule \axiom{eirule} to an integral with this term.
}{
\spadpaste{eirule integral(sin u + exp u/u, u) \free{eirule}}
}
```

Here is one final adornment you will find useful. When matching a pattern of the form `\axiom{x + y}` to an expression containing a long sum of the form `\axiom{a + \ldots + b}`, there is no way to predict in advance which subset of the sum matches `\axiom{x}` and which matches `\axiom{y}`. Aside from efficiency, this is generally unimportant since the rule holds for any possible combination of matches for `\axiom{x}` and `\axiom{y}`. In some situations, however, you may want to say which pattern variable is a sum (or product) of several terms, and which should match only a single term. To do this, put a prefix colon `\axiomSyntax{:}` before the pattern variable that you want to match multiple terms.

```
\xctc{
The remaining rules involve operators \axiom{u} and \axiom{v}.
}{
\spadpaste{u := operator 'u \bound{u}}
}
\xctc{
These definitions tell Axiom that
```

```

\axiom{u} and \axiom{v} are formal operators to be used in expressions.
}{
\spadpaste{v := operator 'v \bound{v}}
}
\xtc{
First define \axiom{myRule}
with no restrictions on the pattern variables
\axiom{x} and \axiom{y}.
}{
\spadpaste{myRule := rule u(x + y) == u x + v y \free{u v}\bound{m}}
}
\xtc{
Apply \axiom{myRule} to an expression.
}{
\spadpaste{myRule u(a + b + c + d) \free{m}}
}
\xtc{
Define \axiom{myOtherRule} to match several terms
so that the rule gets applied recursively.
}{
\spadpaste{myOtherRule := rule u(:x + y) == u x + v y \free{u v}\bound{m2}}
}
\xtc{
Apply \axiom{myOtherRule} to the same expression.
}{
\spadpaste{myOtherRule u(a + b + c + d) \free{m2}}
}

```

Here are some final remarks on pattern matching. Pattern matching provides a very useful paradigm for solving certain classes of problems, namely, those that involve transformations of one form to another and back. However, it is important to recognize its limitations.

First, pattern matching slows down as the number of rules you have to apply increases. Thus it is good practice to organize the sets of rules you use optimally so that irrelevant rules are never included.

Second, careless use of pattern matching can lead to wrong answers. You should avoid using pattern matching to handle hidden algebraic relationships that can go undetected by other programs. As a simple example, a symbol such as ‘J’ can easily be used to represent the square root of $\sqrt{-1}$ or some other important algebraic quantity. Many algorithms branch on whether an expression is zero or not, then divide by that expression if it is not. If you fail to simplify an

expression involving powers of `\axiom{J}` to `\axiom{-1,}` algorithms may incorrectly assume an expression is non-zero, take a wrong branch, and produce a meaningless result.

Pattern matching should also not be used as a substitute for a domain. In Axiom, objects of one domain are transformed to objects of other domains using well-defined `\axiomFun{coerce}` operations. Pattern matching should be used on objects that are all the same type. Thus if your application can be handled by type `\axiomType{Expression}` in Axiom and you think you need pattern matching, consider this choice carefully.

You may well be better served by extending an existing domain or by building a new domain of objects for your application.

This chapter shows how to use the Axiom graphics facilities under the X Window System. Axiom has `\twodim{}` and `\threedim{}` drawing and rendering packages that allow the drawing, coloring, transforming, mapping, clipping, and combining of graphic output from Axiom computations. This facility is particularly useful for investigating problems in areas such as topology. The graphics package is capable of plotting functions of one or more variables or plotting parametric surfaces and curves. Various coordinate systems are also available, such as polar and spherical.

A graph is displayed in a viewport window and it has a control-panel that uses interactive mouse commands. PostScript and other output forms are available so that Axiom images can be printed or used by other programs.^{\footnote{PostScript is a trademark of Adobe Systems Incorporated, registered in the United States.}}

11.0.124 Plotting Two-Dimensional Functions of One Variable

⇒ “notitle” (ugGraphTwoDOptionsPage) 11.0.127 on page 2220

`<ug07.ht>+≡`

```
\begin{page}{ugGraphTwoDPlotPage}
{7.1.1. Plotting Two-Dimensional Functions of One Variable}
\beginscroll
```

The first kind of `\twodim{}` graph is that of a curve defined by a function `\axiom{y = f(x)}` over a finite interval of the `\axiom{x}` axis.

```
%
\beginImportant
The general format for drawing a function defined by a formula
\axiom{f(x)} is:
%
\centerline{{{ \tt draw(f(x), x = a..b, {\it options}) }}}
where \axiom{a..b} defines the range of \axiom{x}, and where
{\it options} prescribes zero or more options as described in
\downlink{‘‘Two-Dimensional Options’’}{ugGraphTwoDOptionsPage}
in Section 7.1.4\ignore{ugGraphTwoDOptions}.
An example of an option is \axiom{curveColor == bright red().}
An alternative format involving functions \axiom{f} and \axiom{g}
is also available.
\endImportant
```

A simple way to plot a function is to use a formula. The first argument is the formula. For the second argument, write the name of the independent variable (here, `\axiom{x}`), followed by an `\spadSyntax{=}`, and the range of values.

```
\psXtc{
Display this formula over the range
\texht{ $0 \leq x \leq 6$ }{ $0 \leq x \leq 6$ }.
Axiom converts your formula to a compiled
function so that the results can be computed
quickly and efficiently.
}{
\graphpaste{draw(sin(tan(x)) - tan(sin(x)),x = 0..6)}
}{
\epsffile[0 0 295 295]{../ps/2d1vara.ps}
}
```

Notice that Axiom compiled the function before the graph was put on the screen.

```

\psXtc{
Here is the same graph on a different interval.
This time we give the graph a title.
}{
\graphpaste{draw(sin(tan(x)) - tan(sin(x)),x = 10..16)}
}{
>window was 300 x 300
\epsffile[0 0 295 295]{../ps/2d1varb.ps}
}
%
Once again the formula is converted to a compiled function before
any points were computed.
If you want to graph the same function on several intervals, it is
a good idea to define the function first so that the function has
to be compiled only once.
\xtc{
This time we first define the function.
}{
\spadpaste{f(x) == (x-1)*(x-2)*(x-3) \bound{f}}
}
\psXtc{
To draw the function, the first argument is its name
and the second is just the range with no independent variable.
}{
\graphpaste{draw(f, 0..4) \free{f}}
}{
\epsffile[0 0 295 295]{../ps/2d1vard.ps}
}

11.0.125 Plotting 2D Parametric Plane Curves

⇒ “notitle” (ugGraphThreeDOptionsPage) 11.0.138 on page 2279

`<ug07.ht>+≡`

```
\begin{page}{ugGraphTwoDParPage}
{7.1.2. Plotting 2D Parametric Plane Curves}
\beginscroll
```

The second kind of `\twodim{}` graph is that of curves produced by parametric equations.

Let `\axiom{x = f(t)}` and `\axiom{y = g(t)}` be formulas or two functions `\axiom{f}` and `\axiom{g}` as the parameter `\axiom{t}` ranges over an interval `\axiom{[a,b]}`.

The function `\axiomFun{curve}` takes the two functions `\axiom{f}` and `\axiom{g}` as its parameters.

`\beginImportant`

The general format for drawing a `\twodim{}` plane curve defined by parametric formulas `\axiom{x = f(t)}` and `\axiom{y = g(t)}` is:

```
%
\centerline{{{ \tt draw(curve(f(t), g(t)), t = a..b, {\it options}) }}}
where \axiom{a..b} defines the range of the independent variable \axiom{t},
and where {\it options} prescribes zero or more options as
described in
\downlink{‘‘Three-Dimensional Options’’}{ugGraphThreeDOptionsPage}
in Section 7.2.4\ignore{ugGraphThreeDOptions}.
An example of an option is \axiom{curveColor == bright red().}
\endImportant
```

Here’s an example:

```
\psXtc{
Define a parametric curve using a range involving
\axiom{\%pi}, Axiom’s way of saying \texht{$\pi$}{{‘‘pi’’}.
For parametric curves, Axiom compiles two
functions, one for each of the functions \axiom{f} and \axiom{g}.
}{
\graphpaste{draw(curve(sin(t)*sin(2*t)*sin(3*t),
sin(4*t)*sin(5*t)*sin(6*t)), t = 0..2*\%pi)}
}{
\epsffile[0 0 295 295]{../ps/2dppca.ps}
}
%
%
```

```

\psXtc{
The title may be an arbitrary string and is an
optional argument to the \axiomFun{draw} command.
}{
\graphpaste{draw(curve(cos(t), sin(t)), t = 0..2*\%pi)}
}{
\epsffile[0 0 295 295]{../ps/2dppcb.ps}
}
%
If you plan on plotting \axiom{x = f(t)}, \axiom{y = g(t)} as \axiom{t}
ranges over several intervals, you may want to define functions
\axiom{f} and \axiom{g} first, so
that they need not be recompiled every time you create a new graph.
Here's an example:
\xtc{
As before, you can first define the functions you wish to draw.
}{
\spadpaste{f(t:DFLOAT):DFLOAT == sin(3*t/4) \bound{f}}
}
\xtc{
Axiom compiles them to map \axiomType{DoubleFloat}
values to \axiomType{DoubleFloat} values.
}{
\spadpaste{g(t:DFLOAT):DFLOAT == sin(t) \bound{g}}
}

\psXtc{
Give to {\tt curve} the names of the functions,
then write the range without the name of the
independent variable.
}{
\graphpaste{draw(curve(f,g),0..\%pi) \free{f g}}
}{
\epsffile[0 0 295 295]{../ps/2dppcc.ps}
}
%
%
\psXtc{
Here is another look at the same curve but over a different
range. Notice that \axiom{f} and \axiom{g} are not recompiled.
Also note that Axiom provides a default title based on
the first function specified in \axiomFun{curve}.
}{
\graphpaste{draw(curve(f,g),-4*\%pi..4*\%pi) \free{f g}}
}{
\epsffile[0 0 295 295]{../ps/2dppce.ps}
}

```

```

}

11.0.126 Plotting Plane Algebraic Curves

⇒ “notitle” (ugGraphTwoDOptionsPage) 11.0.127 on page 2220

```
<ug07.ht>+≡
\begin{page}{ugGraphTwoDPlanePage}{7.1.3. Plotting Plane Algebraic Curves}
\beginscroll
```

A third kind of `\twodim{}` graph is a non-singular ‘‘solution curve’’ in a rectangular region of the plane.

A solution curve is a curve defined by a polynomial equation `\axiom{p(x,y) = 0}`.

Non-singular means that the curve is ‘‘smooth’’ in that it does not cross itself or come to a point (cusp).

Algebraically, this means that for any point `\axiom{(x,y)}` on the curve, that is, a point such that `\axiom{p(x,y) = 0}`, the partial derivatives `\texht{${\partial p \over \partial x}(x,y)$}` and `${\partial p \over \partial y}(x,y)$` `\axiom{dp/dx(x,y)}` and `\axiom{dp/dy(a,b)}` are not both zero.

```
%
\beginImportant
The general format for drawing a non-singular solution curve
given by a polynomial of the form \axiom{p(x,y) = 0} is:
%
\centerline{{\tt draw(p(x,y) = 0, x, y, range == [a..b, c..d],
\it options)}}}
where the second and third arguments name the first and second
independent variables of \axiom{p}.
A {\tt range} option is always given to designate a bounding
rectangular region of the plane \texht{$a \leq x \leq b, c \leq y
\leq d$} {a <= x <= b, c <= y <= d}.
Zero or more additional options as described in
\downlink{‘‘Two-Dimensional Options’’}{ugGraphTwoDOptionsPage}
in Section 7.1.4\ignore{ugGraphTwoDOptions}
may be given.
\endImportant
```

```
\xctc{
We require that the polynomial has rational or integral coefficients.
Here is an algebraic curve example (‘‘Cartesian ovals’’):
}{
\spadpaste{p := ((x**2 + y**2 + 1) - 8*x)**2 -
(8*(x**2 + y**2 + 1)-4*x-1) \bound{p}}
```

```

}

\psXtc{
The first argument is always expressed as an equation of the form
\axiom{p = 0} where \axiom{p} is a polynomial.
}{
\graphpaste{draw(p = 0, x, y, range == [-1..11, -7..7]) \free{p}}

<ug07.ht>+≡
\begin{page}{ugGraphTwoDOptionsPage}{7.1.4. Two-Dimensional Options}
\beginscroll
```

The `\axiomFun{draw}` commands take an optional list of options, such as `{\tt title}` shown above. Each option is given by the syntax: `{\it name} {\tt ==} {\it value}`. Here is a list of the available options in the order that they are described below.

```
\table{ {adaptive} {clip} {unit} {clip} {curveColor} {range}
{toScale} {pointColor} {coordinates}}
```

The `\axiom{adaptive}` option turns adaptive plotting on or off. Adaptive plotting uses an algorithm that traverses a graph and computes more points for those parts of the graph with high curvature. The higher the curvature of a region is, the more points the algorithm computes.

```
%
%
\psXtc{
The {\tt adaptive} option is normally on.
Here we turn it off.
}{
\graphpaste{draw(sin(1/x),x=-2*%\pi..2*%\pi, adaptive == false)}

11.0.128 Color

<ug07.ht>+≡

```
\begin{page}{ugGraphColorPage}{7.1.5. Color}
\beginscroll
```

The domain `\axiomType{Color}` provides operations for manipulating colors in `\twodim{}` graphs. Colors are objects of `\axiomType{Color}`. Each color has a `{\it hue}` and a `{\it weight}`. Hues are represented by integers that range from `\axiom{1}` to the `\axiomFunFrom{numberOfHues(){Color}}`, normally `\axiom{27}`. Weights are floats and have the value `\axiom{1.0}` by default.

```
\indent{0}
\beginitems
%
\item[\axiomFun{color}]{\funArgs{integer}}
creates a color of hue {\it integer} and weight \axiom{1.0}.
%
\item[\axiomFun{hue}]{\funArgs{color}}
returns the hue of {\it color} as an integer.
%
\item[\axiomFun{red}]{\funArgs{}},
\funSyntax{blue}{},
\funSyntax{green}{}, and \funSyntax{yellow}{}
create colors of that hue with weight \axiom{1.0}.
%
\item[\subscriptIt{color}{1} {\tt +} \subscriptIt{color}{2}] returns the
color that results from additively combining the indicated
\subscriptIt{color}{1} and \subscriptIt{color}{2}.
Color addition is not commutative: changing the order of the arguments
produces different results.
%
\item[{\it integer} {\tt *} {\it color}]
changes the weight of {\it color} by {\it integer}
without affecting its hue.
For example,
\axiom{red() + 3*yellow()} produces a color closer to yellow than to red.
Color multiplication is not associative: changing the order of grouping
produces different results.
\enditems

11.0.130 Two-Dimensional Control-Panel

<ug07.ht>+≡

```
\begin{page}{ugGraphTwoDControlPage}{7.1.7. Two-Dimensional Control-Panel}
\beginscroll
```

Once you have created a viewport, move your mouse to the viewport and click with your left mouse button to display a control-panel.

The panel is displayed on the side of the viewport closest to where you clicked. Each of the buttons which toggle on and off show the current state of the graph.

```
\subsubsection{Transformations}
```

Object transformations are executed from the control-panel by mouse-activated potentiometer windows.

```
%
\indent{0}
\beginitems
```

```
\item[Scale:] To scale a graph, click on a mouse button within the
{\bf Scale} window in the upper left corner of the control-panel. The
axes along which the scaling is to occur are indicated by setting the
toggles above the arrow. With {\tt X On} and {\tt Y On} appearing,
both axes are selected and scaling is uniform. If either is not
selected, for example, if {\tt X Off} appears, scaling is non-uniform.
```

```
\item[Translate:] To translate a graph, click the mouse in the {\bf
Translate} window in the direction you wish the graph to move. This
window is located in the upper right corner of the control-panel.
Along the top of the {\bf Translate} window are two buttons for
selecting the direction of translation. Translation along both
coordinate axes results when {\tt X On} and {\tt Y On} appear or along
one axis when one is on, for example, {\tt X On} and {\tt Y Off}
appear.
\enditems

\subsubsection{Messages}
```

The window directly below the transformation potentiometer windows is used to display system messages relating to the viewport and the control-panel. The following format is displayed: \newline

```
\centerline{[[scaleX, scaleY] \axiom{>}}
graph\axiom{<} [translateX, translateY] \newline}}
```

The two values to the left show the scale factor along the $\{X\}$ and $\{Y\}$ coordinate axes. The two values to the right show the distance of translation from the center in the $\{X\}$ and $\{Y\}$ directions. The number in the center shows which graph in the viewport this data pertains to. When multiple graphs exist in the same viewport, the graph must be selected (see ‘Multiple Graphs,’ below) in order for its transformation data to be shown, otherwise the number is 1.

`\subsubsection{Multiple Graphs}`

The `\bf Graphs` window contains buttons that allow the placement of `\twodim` graphs into one of nine available slots in any other `\twodim` viewport. In the center of the window are numeral buttons from one to nine that show whether a graph is displayed in the viewport. Below each number button is a button showing whether a graph that is present is selected for application of some transformation. When the caret symbol is displayed, then the graph in that slot will be manipulated. Initially, the graph for which the viewport is created occupies the first slot, is displayed, and is selected.

```
%
\indent{0}
\beginitems
```

`\item[Clear:]` The `\bf Clear` button deselects every viewport graph slot. A graph slot is reselected by selecting the button below its number.

`\item[Query:]` The `\bf Query` button is used to display the scale and translate data for the indicated graph. When this button is selected the message ‘Click on the graph to query’ appears. Select a slot number button from the `\bf Graphs` window. The scaling factor and translation offset of the graph are then displayed in the message window.

`\item[Pick:]` The `\bf Pick` button is used to select a graph to be placed or dropped into the indicated viewport. When this button is selected, the message ‘Click on the graph to pick’ appears. Click on the slot with the graph number of the desired graph. The graph information is held waiting for you to execute a `\bf Drop` in some other graph.

`\item[Drop:]` Once a graph has been picked up using the `\bf Pick` button, the `\bf Drop` button places it into a new viewport slot.

The message ‘Click on the graph to drop’ appears in the message window when the `{\bf Drop}` button is selected.

By selecting one of the slot number buttons in the `{\bf Graphs}` window, the graph currently being held is dropped into this slot and displayed.

11.0.131 Operations for Two-Dimensional Graphics

<ug07.ht>+≡

```
\begin{page}{ugGraphTwoDopsPage}
{7.1.8. Operations for Two-Dimensional Graphics}
\beginscroll
```

Here is a summary of useful Axiom operations for `\twodim{}` graphics.
 Each operation name is followed by a list of arguments.
 Each argument is written as a variable informally named according to the type of the argument (for example, `{\it integer}`).
 If appropriate, a default value for an argument is given in parentheses immediately following the name.

```
%
\texht{\bgroup\hbadness = 10001\sloppy}{ }
\indent{0}
\beginitems
%
\item[\axiomFun{adaptive}]{\funArgs{\optArg{boolean\argDef{true}}}}
sets or indicates whether graphs are plotted
according to the adaptive refinement algorithm.

\item[\axiomFun{axesColorDefault}]{\funArgs{\optArg{color\argDef{dark
blue()}}}} sets or indicates the default color of the axes in a
\twodim{ } graph viewport.

\item[\axiomFun{clipPointsDefault}]{\funArgs{\optArg{boolean\argDef{false}}}}
sets or
indicates whether point clipping is
to be applied as the default for graph plots.
%
\item[\axiomFun{drawToScale}]{\funArgs{\optArg{boolean\argDef{false}}}}
sets or
indicates whether the plot of a graph
is ‘‘to scale’’ or uses the entire viewport space as the default.

\item[\axiomFun{lineColorDefault}]{\funArgs{\optArg{color\argDef{pastel
yellow()}}}} sets or indicates the default color of the lines or curves
in a \twodim{ } graph viewport.

\item[\axiomFun{maxPoints}]{\funArgs{\optArg{integer\argDef{500}}}}
sets or indicates
the default maximum number of
possible points to be used when constructing a \twodim{ } graph.
```

```

%
\item[\axiomFun{minPoints}]\funArgs{\optArg{integer\argDef{21}}}}
sets or indicates the default minimum number of
possible points to be used when constructing a \twodim{} graph.

\item[\axiomFun{pointColorDefault}]\funArgs{\optArg{color\argDef{bright
red()}}}} sets or indicates the default color of the points in a
\twodim{} graph viewport.

\item[\axiomFun{pointSizeDefault}]\funArgs{\optArg{integer\argDef{5}}}}
sets or indicates the default size of the
dot used to plot points in a \twodim{} graph.
%
\item[\axiomFun{screenResolution}]\funArgs{\optArg{integer\argDef{600}}}}
sets or indicates the default screen
resolution constant used in setting the computation limit of adaptively
generated curve plots.

\item[\axiomFun{unitsColorDefault}]\funArgs{\optArg{color\argDef{dim
green()}}}} sets or indicates the default color of the unit labels in a
\twodim{} graph viewport.

\item[\axiomFun{viewDefaults}]\funArgs{}
resets the default settings for the following
attributes: point color, line color, axes color, units color, point size,
viewport upper left-hand corner position, and the viewport size.

\item[\axiomFun{viewPosDefault}]\funArgs{\optArg{list\argDef{[100,100]}}}}
sets or indicates the default position of the upper left-hand corner
of a \twodim{} viewport, relative to the display root window. The
upper left-hand corner of the display is considered to be at the (0,
0) position.

\item[\axiomFun{viewSizeDefault}]\funArgs{\optArg{list\argDef{[200,200]}}}}
sets or indicates the default size in which two dimensional viewport
windows are shown. It is defined by a width and then a height.

\item[\axiomFun{viewWriteAvailable}]\funArgs{\optArg{list\argDef{["pixmap",
"bitmap", "postscript", \image]}}}} indicates the possible file types
that can be created with the
\axiomFunFrom{write}{TwoDimensionalViewport} function.

\item[\axiomFun{viewWriteDefault}]
\funArgs{\optArg{list\argDef{[]}}}}
sets or indicates the default types of files, in
addition to the {\bf data} file, that are created when a

```

`\axiomFun{write}` function is executed on a viewport.

`\item[\axiomFun{units}]\funArgs{viewport, integer\argDef{1}, string\argDef{"off"}}` turns the units on or off for the graph with index `{\it integer}`.

`\item[\axiomFun{axes}]`

`\funArgs{viewport, integer\argDef{1}, string\argDef{"on"}}`

turns the axes on

or off for the graph with index `{\it integer}`.

%

`\item[\axiomFun{close}]\funArgs{viewport}`

closes `{\it viewport}`.

%

`\item[\axiomFun{connect}]`

`\funArgs{viewport, integer\argDef{1}, string\argDef{"on"}}`

declares whether lines

connecting the points are displayed or not.

%

`\item[\axiomFun{controlPanel}]\funArgs{viewport, string\argDef{"off"}}`

declares

whether the `\twodim{}` control-panel is automatically displayed

or not.

%

`\item[\axiomFun{graphs}]\funArgs{viewport}`

returns a list

describing the state of each graph.

If the graph state is not being used this is shown by `{\tt "undefined"}`,

otherwise a description of the graph's contents is shown.

%

`\item[\axiomFun{graphStates}]\funArgs{viewport}`

displays

a list of all the graph states available for `{\it viewport}`, giving the values for every property.

%

`\item[\axiomFun{key}]\funArgs{viewport}`

returns the process

ID number for `{\it viewport}`.

%

`\item[\axiomFun{move}]\funArgs{viewport,`

`\subscriptText{integer}{x}(viewPosDefault),`

`\subscriptText{integer}{y}(viewPosDefault)}`

moves `{\it viewport}` on the screen so that the

upper left-hand corner of `{\it viewport}` is at the position `{\it (x,y)}`.

%

`\item[\axiomFun{options}]\funArgs{\it viewport}`

```

returns a list
of all the \axiomType{DrawOption}s used by {\it viewport}.
%
\item[\axiomFun{points}]
\funArgs{viewport, integer\argDef{1}, string\argDef{"on"}}
specifies whether the graph points for graph {\it integer} are
to be displayed or not.
%
\item[\axiomFun{region}]
\funArgs{viewport, integer\argDef{1}, string\argDef{"off"}}
declares whether graph {\it integer} is or is not to be displayed
with a bounding rectangle.
%
\item[\axiomFun{reset}]\funArgs{viewport}
resets all the properties of {\it viewport}.
%
\item[\axiomFun{resize}]\funArgs{viewport,
\subscriptText{integer}{width}, \subscriptText{integer}{height}}
resizes {\it viewport} with a new {\it width} and {\it height}.
%
\item[\axiomFun{scale}]\funArgs{viewport, \subscriptText{integer}{n}\argDef{1},
\subscriptText{integer}{x}
\argDef{0.9}, \subscriptText{integer}{y}\argDef{0.9}}
scales values for the
{\it x} and {\it y} coordinates of graph {\it n}.
%
\item[\axiomFun{show}]\funArgs{viewport, \subscriptText{integer}{n}\argDef{1},
string\argDef{"on"}}
indicates if graph {\it n} is shown or not.
%
\item[\axiomFun{title}]\funArgs{viewport, string\argDef{"Axiom 2D"}}
designates the title for {\it viewport}.
%
\item[\axiomFun{translate}]\funArgs{viewport,
\subscriptText{integer}{n}\argDef{1},
\subscriptText{float}{x}
\argDef{0.0}, \subscriptText{float}{y}\argDef{0.0}}
causes graph {\it n} to be moved {\it x}
and {\it y} units in the respective directions.
%
\item[\axiomFun{write}]\funArgs{viewport,
\subscriptText{string}{directory},
\optArg{strings}}
if no third argument is given, writes the

```

`{\bf data}` file onto the directory
with extension `{\bf data}`.
The third argument can be a single string
or a list of strings with some or
all the entries `{\tt "pixmap"}`, `{\tt "bitmap"}`,
`{\tt "postscript"}`, and
`{\tt "image"}`.

11.0.132 Addendum: Building Two-Dimensional Graphs

<ug07.ht>+≡

```
\begin{page}{ugGraphTwoDbuildPage}
{7.1.9. Addendum: Building Two-Dimensional Graphs}
\beginscroll
```

In this section we demonstrate how to create `\twodim{}` graphs from lists of points and give an example showing how to read the lists of points from a file.

```
\subsubsection{Creating a Two-Dimensional Viewport from a List of Points}
```

Axiom creates lists of points in a `\twodim{}` viewport by utilizing the `\axiomType{GraphImage}` and `\axiomType{TwoDimensionalViewport}` domains. In this example, the `\axiomFunFrom{makeGraphImage}{GraphImage}` function takes a list of lists of points parameter, a list of colors for each point in the graph, a list of colors for each line in the graph, and a list of sizes for each point in the graph.

```
\xctc{
The following expressions create a list of lists of points which will
be read by Axiom and made into a \twodim{} viewport.
}{
\spadpaste{p1 := point [1,1]\$(Point DFLOAT) \bound{p1}}
}
\xctc{
}{
\spadpaste{p2 := point [0,1]\$(Point DFLOAT) \bound{p2}}
}
\xctc{
}{
\spadpaste{p3 := point [0,0]\$(Point DFLOAT) \bound{p3}}
}
\xctc{
}{
\spadpaste{p4 := point [1,0]\$(Point DFLOAT) \bound{p4}}
}
\xctc{
}{
\spadpaste{p5 := point [1,.5]\$(Point DFLOAT) \bound{p5}}
}
\xctc{
}{
\spadpaste{p6 := point [.5,0]\$(Point DFLOAT) \bound{p6}}
}
```

```

\xtc{
}{
\spadpaste{p7 := point [0,0.5]\$(Point DFLOAT) \bound{p7}}
}
\xtc{
}{
\spadpaste{p8 := point [.5,1]\$(Point DFLOAT) \bound{p8}}
}
\xtc{
}{
\spadpaste{p9 := point [.25,.25]\$(Point DFLOAT) \bound{p9}}
}
\xtc{
}{
\spadpaste{p10 := point [.25,.75]\$(Point DFLOAT) \bound{p10}}
}
\xtc{
}{
\spadpaste{p11 := point [.75,.75]\$(Point DFLOAT) \bound{p11}}
}
\xtc{
}{
\spadpaste{p12 := point [.75,.25]\$(Point DFLOAT) \bound{p12}}
}
\xtc{
Finally, here is the list.
}{
\spadpaste{llp := [[p1,p2], [p2,p3], [p3,p4], [p4,p1], [p5,p6], [p6,p7],
[p7,p8], [p8,p5], [p9,p10], [p10,p11], [p11,p12], [p12,p9]]
\free{p1 p2 p3 p4 p5 p6 p7 p8 p9 p10 p11 p12} \bound{llp}}
}
\xtc{
Now we set the point sizes for all components of the graph.
}{
\spadpaste{size1 := 6::PositiveInteger \bound{size1}}
}
\xtc{
}{
}
\xtc{
}{
\spadpaste{size2 := 8::PositiveInteger \bound{size2}}
}
\xtc{
}{
\spadpaste{size3 := 10::PositiveInteger \bound{size3}}
}

```

```

}
\xtc{
}{
\spadpaste{lsize := [size1, size1, size1, size1, size2, size2, size2,
size2, size3, size3, size3, size3] \bound{lsize} \free{size1 size2 size3}}
}
\xtc{
Here are the colors for the points.
}{
\spadpaste{pc1 := pastel red() \bound{pc1}}
}
\xtc{
}{
\spadpaste{pc2 := dim green() \bound{pc2}}
}
\xtc{
}{
\spadpaste{pc3 := pastel yellow() \bound{pc3}}
}
\xtc{
}{
\spadpaste{lpc := [pc1, pc1, pc1, pc1, pc2, pc2, pc2, pc2, pc3, pc3,
pc3, pc3] \free{pc1 pc2 pc3} \bound{lpc}}
}
\xtc{
Here are the colors for the lines.
}{
\spadpaste{lc := [pastel blue(), light yellow(), dim green(),
bright red(), light green(), dim yellow(), bright blue(),
dark red(), pastel red(), light blue(), dim green(),
light yellow()] \bound{lc}}
}
\xtc{
Now the \axiomType{GraphImage} is created according to the component
specifications indicated above.
}{
\spadpaste{g := makeGraphImage(llp,lpc,lc,lsize)\$GRIMAGE
\bound{g} \free{llp lpc lc lsize}}
}
\psXtc{
The \axiomFunFrom{makeViewport2D}{TwoDimensionalViewport} function now
creates a \axiomType{TwoDimensionalViewport} for this graph according to the
list of options specified within the brackets.
}{
\graphpaste{makeViewport2D(g,[title("Lines")])\$VIEW2D \free{g}}
}

```

```

%
}
%See Figure #.#.
\xtc{
This example demonstrates the use of the \axiomType{GraphImage}
functions \axiomFunFrom{component}{GraphImage} and
\axiomFunFrom{appendPoint}{GraphImage} in adding points to an empty
\axiomType{GraphImage}.
}{
\spadpaste{clear all \bound{clearAll}}
}
\xtc{
}{
\spadpaste{g := graphImage()\$GRIMAGE \bound{Sg}\free{clearAll}}
}
\xtc{
}{
\spadpaste{p1 := point [0,0]\$(Point DFLOAT) \bound{Sp1}}
}
\xtc{
}{
\spadpaste{p2 := point [.25,.25]\$(Point DFLOAT) \bound{Sp2}}
}
\xtc{
}{
\spadpaste{p3 := point [.5,.5]\$(Point DFLOAT) \bound{Sp3}}
}
\xtc{
}{
\spadpaste{p4 := point [.75,.75]\$(Point DFLOAT) \bound{Sp4}}
}
\xtc{
}{
\spadpaste{p5 := point [1,1]\$(Point DFLOAT) \bound{Sp5}}
}
\xtc{
}{
\spadpaste{component(g,p1)\$GRIMAGE\free{Sg Sp1}\bound{gp1}}
}
\xtc{
}{
\spadpaste{component(g,p2)\$GRIMAGE\free{Sg Sp2}\bound{gp2}}
}
\xtc{
}{
\spadpaste{appendPoint(g,p3)\$GRIMAGE\free{gp1 gp2 Sp3}\bound{gp3}}
}

```

```

}
\xtc{
}{
\spadpaste{appendPoint(g,p4)\$GRIMAGE\free{gp3 Sp4}\bound{gp4}}
}
\xtc{
}{
\spadpaste{appendPoint(g,p5)\$GRIMAGE\free{gp4 Sp5}\bound{gp5}}
}
\xtc{
}{
\spadpaste{g1 := makeGraphImage(g)\$GRIMAGE \bound{Sg1} \free{gp5}}
}
\psXtc{
Here is the graph.
}{
\graphpaste{makeViewport2D(g1,[title("Graph Points")])\$VIEW2D \free{Sg1}}
}{
%
}
%
%See Figure #.#.
%
\xtc{
A list of points can also be made into a \axiomType{GraphImage} by
using the operation \axiomFunFrom{coerce}{GraphImage}. It is
equivalent to adding each point to \axiom{g2} using
\axiomFunFrom{component}{GraphImage}.
}{
\spadpaste{g2 := coerce([p1],[p2],[p3],[p4],[p5])\$GRIMAGE
\free{Sp1 Sp2 Sp3 Sp4 Sp5} \bound{Sg2}}
}
\xtc{
Now, create an empty \axiomType{TwoDimensionalViewport}.
}{
\spadpaste{v := viewport2D()\$VIEW2D \bound{Sv}}
}
\xtc{
}{
\spadpaste{options(v,[title("Just Points")])\$VIEW2D \free{Sv}\bound{Svo}}
}
\xtc{
Place the graph into the viewport.
}{
\spadpaste{putGraph(v,g2,1)\$VIEW2D \free{Sg2 Svo}\bound{Svog2}}
}

```

%See Figure #.#.

The following three functions read a list of points from a file and then draw the points and the connecting lines. The points are stored in the file in readable form as floating point numbers (specifically, `\axiomType{DoubleFloat}` values) as an alternating stream of `\axiom{x}`- and `\axiom{y}`-values. For example,

\beginImportant

```
\noindent
{\tt 1.\ \ \ drawPoints(lp>List\ Point\ DoubleFloat):VIEW2D\ ==}\newline
{\tt 2.\ \ \ \ g\ :=\ graphImage()\$GRIMAGE}\newline
{\tt 3.\ \ \ \ \ for\ p\ in\ lp\ repeat}\newline
{\tt 4.\ \ \ \ \ \ }
component(g,p,pointColorDefault(),lineColorDefault(),)\newline
{\tt 5.\ \ \ \ \ \ \ pointSizeDefault())}\newline
{\tt 6.\ \ \ \ \ gi\ :=\ makeGraphImage(g)\$GRIMAGE}\newline
{\tt 7.\ \ \ \ \ makeViewport2D(gi,[title("Points")])\$VIEW2D}\newline
{\tt 8.\ \ \ }\newline
{\tt 9.\ \ \ drawLines(lp>List\ Point\ DoubleFloat):VIEW2D\ ==}\newline
{\tt 10.\ \ \ \ g\ :=\ graphImage()\$GRIMAGE}\newline
{\tt 11.\ \ \ \ }
component(g,\ lp,\ pointColorDefault(),\ lineColorDefault(),)\newline
{\tt 12.\ \ \ \ \ \ pointSizeDefault())\$GRIMAGE}\newline
{\tt 13.\ \ \ \ \ gi\ :=\ makeGraphImage(g)\$GRIMAGE}\newline
{\tt 14.\ \ \ \ \ makeViewport2D(gi,[title("Points")])\$VIEW2D}\newline
{\tt 15.\ \ \ }\newline
{\tt 16.\ \ plotData2D(name,\ title)\ ==}\newline
{\tt 17.\ \ \ \ f:File(DFLOAT)\ :=\ open(name,"input")}\newline
{\tt 18.\ \ \ \ lp:LIST(Point\ DFLOAT)\ :=\ empty()}\newline
```

```
{\tt 19.\ \ \ \ \
while\ ((x :=\ readIfCan!(f))\ case\ DFLOAT)\ repeat}\newline
{\tt 20.\ \ \ \ \ \ y\ :=\ DFLOAT\ :=\ read!(f)}\newline
{\tt 21.\ \ \ \ \ \
lp\ :=\ cons(point\ [x,y]\$(Point\ DFLOAT),\ lp)}\newline
{\tt 22.\ \ \ \ \ \ lp}\newline
{\tt 23.\ \ \ \ \ close!(f)}\newline
{\tt 24.\ \ \ \ \ drawPoints(lp)}\newline
{\tt 25.\ \ \ \ \ drawLines(lp)}\newline
\endImportant
%
This command will actually create the viewport and the graph if
the point data is in the file \axiom{"file.data"}.
\beginImportant

\noindent
{\tt 1.\ \ \ \ plotData2D("file.data",\ "2D\ Data\ Plot")}\newline
\endImportant

11.0.133 Addendum: Appending a Graph to a Viewport Window Containing a Graph

<ug07.ht>+≡

```
\begin{page}{ugGraphTwoDappendPage}
{7.1.10. Addendum: Appending a Graph to a Viewport
Window Containing a Graph}
\beginscroll
```

This section demonstrates how to append a `\twodim{}` graph to a viewport already containing other graphs. The default `\axiomFun{draw}` command places a graph into the first `\axiomType{GraphImage}` slot position of the `\axiomType{TwoDimensionalViewport}`.

```
\xtc{
This graph is in the first slot in its viewport.
}{
\spadpaste{v1 := draw(sin(x),x=0..2*%\pi) \bound{v1}}
}
\xtc{
So is this graph.
}{
\spadpaste{v2 := draw(cos(x),x=0..2*%\pi, curveColor==light red())
\bound{v2}}
}
\xtc{
The operation \axiomFunFrom{getGraph}{TwoDimensionalViewport}
retrieves the \axiomType{GraphImage} \axiom{g1} from the first slot
position in the viewport \axiom{v1}.
}{
\spadpaste{g1 := getGraph(v1,1) \bound{g1}\free{v1}}
}
\xtc{
Now \axiomFunFrom{putGraph}{TwoDimensionalViewport}
places \axiom{g1} into the the second slot position of \axiom{v2}.
}{
\spadpaste{putGraph(v2,g1,2) \bound{v22}\free{g1 v2}}
}
\psXtc{
Display the new \axiomType{TwoDimensionalViewport} containing both graphs.
}{
\graphpaste{makeViewport2D(v2) \free{v22}}
}{
%
}
%
}
```

```
%See Figure #.#.
%

11.0.135 Plotting Three-Dimensional Functions of Two Variables

⇒ “notitle” (ugGraphThreeDOptionsPage) 11.0.138 on page 2279

`<ug07.ht>+≡`

```
\begin{page}{ugGraphThreeDPlotPage}
{7.2.1. Plotting Three-Dimensional Functions of Two Variables}
\beginscroll
```

The simplest `\threedim{}` graph is that of a surface defined by a function of two variables, `\axiom{z = f(x,y)}`.

`\beginImportant`

The general format for drawing a surface defined by a formula `\axiom{f(x,y)}` of two variables `\axiom{x}` and `\axiom{y}` is:

```
\centerline{{\tt draw(f(x,y), x = a..b, y = c..d, {\it options})}}
where \axiom{a..b} and \axiom{c..d} define the range of \axiom{x}
and \axiom{y}, and where {\it options} prescribes zero or more
options as described in
\downlink{‘‘Three-Dimensional Options’’}{ugGraphThreeDOptionsPage}
in Section 7.2.4\ignore{ugGraphThreeDOptions}.
An example of an option is \axiom{title == "Title of Graph"}.
An alternative format involving a function \axiom{f} is also
available.
\endImportant
```

```
%
\psXtc{
The simplest way to plot a function of two variables is to use a formula.
With formulas you always precede the range specifications with
the variable name and an \spadSyntax{=} sign.
}{
\graphpaste{draw(cos(x*y),x=-3..3,y=-3..3)}
}{
\epsffile[0 0 295 295]{../ps/3d2vara.ps}
}
%
\xtc{
If you intend to use a function more than once,
or it is long and complex, then first
give its definition to Axiom.
```

```

}{
\spadpaste{f(x,y) == sin(x)*cos(y) \bound{f}}
}
%
%
\psXtc{
To draw the function, just give its name and drop the variables
from the range specifications.
Axiom compiles your function for efficient computation
of data for the graph.
Notice that Axiom uses the text of your function as a
default title.
}{

⇒ “notitle” (ugGraphCoordPage) 11.0.141 on page 2307

ug07.ht+≡

```
\begin{page}{ugGraphThreeDParPage}
{7.2.3. Plotting 3D Parametric Surfaces}
\beginscroll
```

A third kind of `\threedim{}` graph is a surface defined by parametric equations for `\axiom{x(u,v)}`, `\axiom{y(u,v)}`, and `\axiom{z(u,v)}` of two independent variables `\axiom{u}` and `\axiom{v}`.

```
%
\beginImportant
The general format for drawing a \threedim{} graph defined by
parametric formulas \axiom{x = f(u,v)}, \axiom{y = g(u,v)},
and \axiom{z = h(u,v)} is:
%
\centerline{{\tt draw(surface(f(u,v),g(u,v),h(u,v)),
u = a..b, v = c..d, {\it options})}}
where \axiom{a..b} and \axiom{c..d} define the range of the
independent variables \axiom{u} and \axiom{v}, and where
{\it options} prescribes zero or more options as described in
\downlink{‘‘Three-Dimensional Options’’}{ugGraphThreeDOptionsPage}
in Section 7.2.4\ignore{ugGraphThreeDOptions}.
An example of an option is \axiom{title == "Title of Graph".}
An alternative format involving functions \axiom{f}, \axiom{g} and
\axiom{h} is also available.
\endImportant
```

```
%
\psXtc{
This example draws a graph of a surface plotted using the
parabolic cylindrical coordinate system option.
The values of the functions supplied to \axiomFun{surface} are
interpreted in coordinates as given by a {\tt coordinates} option,
here as parabolic cylindrical coordinates (see
\downlink{‘‘Coordinate System Transformations’’}{ugGraphCoordPage}
in Section 7.2.7\ignore{ugGraphCoord}).
}{
\graphpaste{draw(surface(u*cos(v), u*sin(v), v*cos(u)),
u=-4..4, v=0..\%pi, coordinates== parabolicCylindrical)}
}
```

```

\epsffile[0 0 295 295]{../ps/3dpsa.ps}
}
%
Again, you can graph these parametric surfaces using functions,
if the functions are long and complex.
\xtc{
Here we declare the types of arguments and values to be of type
\axiomType{DoubleFloat}.
}{
\spadpaste{n1(u:DFLOAT,v:DFLOAT):DFLOAT == u*cos(v) \bound{n1}}
}
\xtc{
As shown by previous examples, these declarations are necessary.
}{
\spadpaste{n2(u:DFLOAT,v:DFLOAT):DFLOAT == u*sin(v) \bound{n2}}
}
\xtc{
In either case, Axiom compiles the functions
when needed to graph a result.
}{
\spadpaste{n3(u:DFLOAT,v:DFLOAT):DFLOAT == u \bound{n3}}
}
\xtc{
Without these declarations, you have to suffix floats
with \axiom{@DFLOAT} to get a \axiomType{DoubleFloat} result.
However, a call here with an unadorned float
produces a \axiomType{DoubleFloat}.
}{
\spadpaste{n3(0.5,1.0)\free{n3}}
}
%
%
\psXtc{
Draw the surface by referencing the function names, this time
choosing the toroidal coordinate system.
}{
\graphpaste{draw(surface(n1,n2,n3), 1..4, 1..2*%\pi,
coordinates == toroidal(1\DFLOAT)) \free{n1 n2 n3}}
}{

11.0.138 Three-Dimensional Options

⇒ “notitle” (ugGraphCoordPage) 11.0.141 on page 2307

```
<ug07.ht>+≡
\begin{page}{ugGraphThreeDOptionsPage}{7.2.4. Three-Dimensional Options}
\beginscroll
```

The `\axiomFun{draw}` commands optionally take an optional list of options such as `{\tt coordinates}` as shown in the last example. Each option is given by the syntax: `\axiom{name} {\tt ==} \axiom{value}`. Here is a list of the available options in the order that they are described below:

```
\table{ {title} {coordinates} {var1Steps} {style} {tubeRadius} {var2Steps}
{colorFunction} {tubePoints} {space}}
```

```
\psXtc{
The option \axiom{title} gives your graph a title.
}{
\graphpaste{draw(cos(x*y),x=0..2*\%pi,y=0..\%pi,title == "Title of Graph") }
}{
\epsffile[0 0 295 295]{../ps/3doptttl.ps}
}
%
\psXtc{
The \axiom{style} determines which of four rendering algorithms is used for
the graph.
The choices are
{\tt "wireMesh"}, {\tt "solid"}, {\tt "shade"}, and {\tt "smooth"}.
}{
\graphpaste{draw(cos(x*y),x=-3..3,y=-3..3, style=="smooth",
title=="Smooth Option")}
}{
\epsffile[0 0 295 295]{../ps/3doptsty.ps}
}
%
}
```

In all but the wire-mesh style, polygons in a surface or tube plot are normally colored in a graph according to their `\axiom{z}`-coordinate value. Space curves are colored according to their parametric variable value.

To change this, you can give a coloring function.

The coloring function is sampled across the range of its arguments, then normalized onto the standard Axiom colormap.

```

\xtc{
A function of one variable makes the color depend on the
value of the parametric variable specified for a tube plot.
}{
\spadpaste{color1(t) == t \bound{colorFxn1}}
}
\psXtc{
}{
\graphpaste{draw(curve(sin(t), cos(t),0), t=0..2*%pi,
tubeRadius == .3, colorFunction == color1) \free{colorFxn1}}
}{
\epsffile[0 0 295 295]{../ps/3doptcf1.ps}
}
%
\xtc{
A function of two variables makes the color depend on the
values of the independent variables.
}{
\spadpaste{color2(u,v) == u**2 - v**2 \bound{colorFxn2}}
}
\psXtc{
Use the option {\tt colorFunction} for special coloring.
}{
\graphpaste{draw(cos(u*v), u=-3..3, v=-3..3,
colorFunction == color2) \free{colorFxn2}}
}{
\epsffile[0 0 295 295]{../ps/3doptcf2.ps}
}
%
\xtc{
With a three variable function, the
color also depends on the value of the function.
}{
\spadpaste{color3(x,y,fx) == sin(x*fx) + cos(y*fx) \bound{colorFxn3}}
}
\psXtc{
}{
\graphpaste{draw(cos(x*y), x=-3..3, y=-3..3, colorFunction == color3)
\free{colorFxn3}}
}{
\epsffile[0 0 295 295]{../ps/3doptcf3.ps}
}
%
Normally the Cartesian coordinate system is used.
To change this, use the {\tt coordinates} option.

```

For details, see
`\downlink{'Coordinate System Transformations'}{ugGraphCoordPage}`
 in Section 7.2.7\ignore{ugGraphCoord}.

```
%
%
\xtc{
}{
\spadpaste{m(u:DFLOAT,v:DFLOAT):DFLOAT == 1 \bound{m}}
}
\psXtc{
Use the spherical
coordinate system.
}{

}
%
Space curves may be displayed as tubes with polygonal cross sections.
Two options, {\tt tubeRadius} and {\tt tubePoints}, control the size and
shape of this cross section.
%
\psXtc{
The {\tt tubeRadius} option specifies the radius of the tube that
encircles the specified space curve.
}{
\graphpaste{draw(curve(sin(t),cos(t),0),t=0..2*\%pi, style=="shade",
tubeRadius == .3)}
}{
\epsffile[0 0 295 295]{../ps/3doptrrad.ps}
}
%
%
\psXtc{
The {\tt tubePoints} option specifies the number of vertices
defining the polygon that is used to create a tube around the
specified space curve.
The larger this number is, the more cylindrical the tube becomes.
}{
\graphpaste{draw(curve(sin(t), cos(t), 0), t=0..2*\%pi, style=="shade",
tubeRadius == .25, tubePoints == 3)}
}{
\epsffile[0 0 295 295]{../ps/3doptpts.ps}
}
%
%
```

```

%
%
\psXtc{
Options \axiomFunFrom{var1Steps}{DrawOption} and
\axiomFunFrom{var2Steps}{DrawOption} specify the number of intervals into
which the grid defining a surface plot is subdivided with respect to the
first and second parameters of the surface function(s).
}{
\graphpaste{draw(cos(x*y),x=-3..3,y=-3..3, style=="shade", var1Steps == 30,
var2Steps == 30)}
}{
\epsffile[0 0 295 295]{../ps/3doptvb.ps}
}
%
The {\tt space} option
of a \axiomFun{draw} command lets you build multiple graphs in three space.
To use this option, first create an empty three-space object,
then use the {\tt space} option thereafter.
There is no restriction as to the number or kinds
of graphs that can be combined this way.
\xtc{
Create an empty three-space object.
}{
\spadpaste{s := create3Space()\$(ThreeSpace DFLOAT) \bound{s}}
}
%
%
\xtc{
}{
\spadpaste{m(u:DFLOAT,v:DFLOAT):DFLOAT == 1 \bound{m}}
}
\psXtc{
Add a graph to this three-space object.
The new graph destructively inserts the graph
into \axiom{s}.
}{
\graphpaste{
draw(m,0..\%pi,0..2*\%pi, coordinates == spherical, space == s) \free{s m}}
}{
\epsffile[0 0 295 295]{../ps/3dmult1a.ps}
}
%
%
\psXtc{
Add a second graph to \axiom{s}.
}{

```

```

\graphpaste{v := draw(curve(1.5*sin(t), 1.5*cos(t),0), t=0..2*\%pi,
tubeRadius == .25, space == s) \free{s} \bound{v}}
}{
\epsffile[0 0 295 295]{../ps/3dmult1b.ps}
}
%
A three-space object can also be obtained from an existing
\threedim{} viewport
using the \axiomFunFrom{subspace}{ThreeSpace} command.
You can then use \axiomFun{makeViewport3D} to create a viewport window.
\xtc{
Assign to \axiom{subsp} the three-space object in viewport \axiom{v}.
}{
\spadpaste{subsp := subspace v \free{v} \bound{su}}
}
\xtc{
Reset the space component of \axiom{v} to the value of \axiom{subsp}.
}{
\spadpaste{subspace(v, subsp) \bound{sp} \free{su}}

11.0.139 The makeObject Command

<ug07.ht>+≡

```
\begin{page}{ugGraphMakeObjectPage}{7.2.5. The makeObject Command}
\beginscroll
```

An alternate way to create multiple graphs is to use

`\axiomFun{makeObject}`.

The `\axiomFun{makeObject}` command is similar to the `\axiomFun{draw}` command, except that it returns a three-space object rather than a `\axiomType{ThreeDimensionalViewport}`.

In fact, `\axiomFun{makeObject}` is called by the `\axiomFun{draw}` command to create the `\axiomType{ThreeSpace}` then

`\axiomFunFrom{makeViewport3D}{ThreeDimensionalViewport}` to create a viewport window.

```
\xtc{
}{
\spadpaste{m(u:DFLOAT,v:DFLOAT):DFLOAT == 1 \bound{m}}
}
\noOutputXtc{
Do the last example a new way.
First use \axiomFun{makeObject} to
create a three-space object \axiom{sph}.
}{
\spadpaste{sph := makeObject(m, 0..%pi, 0..2*%pi,
coordinates==spherical)\bound{sph}\free{m}}
}
\noOutputXtc{
Add a second object to \axiom{sph}.
}{
\spadpaste{makeObject(curve(1.5*sin(t), 1.5*cos(t), 0),
t=0..2*%pi, space == sph, tubeRadius == .25) \free{sph}\bound{v1}}
}
\noOutputXtc{
Create and display a viewport
containing \axiom{sph}.
}{
\graphpaste{makeViewport3D(sph,"Multiple Objects") \free{v1}}
}
```

Note that an undefined `\axiomType{ThreeSpace}` parameter declared in a `\axiomFun{makeObject}` or `\axiomFun{draw}` command results in an error. Use the `\axiomFunFrom{create3Space}{ThreeSpace}` function to define a `\axiomType{ThreeSpace}`, or obtain a `\axiomType{ThreeSpace}` that has been previously generated before including it in a command line.

11.0.140 Building 3D Objects From Primitives

<ug07.ht>+≡

```
\begin{page}{ugGraphThreeDBuildPage}
{7.2.6. Building 3D Objects From Primitives}
\beginscroll
```

Rather than using the `\axiomFun{draw}` and `\axiomFun{makeObject}` commands, you can create `\threedim{}` graphs from primitives.

Operation `\axiomFunFrom{create3Space}{ThreeSpace}` creates a three-space object to which points, curves and polygons can be added using the operations from the `\axiomType{ThreeSpace}` domain.

The resulting object can then be displayed in a viewport using `\axiomFunFrom{makeViewport3D}{ThreeDimensionalViewport}`.

```
\xctc{
Create the empty three-space object \axiom{space}.
}{
\spadpaste{space := create3Space()\$(ThreeSpace DFLOAT) \bound{space}}
}
```

Objects can be sent to this `\axiom{space}` using the operations exported by the `\axiomType{ThreeSpace}` domain.

The following examples place curves into `\axiom{space}`.

```
\xctc{
Add these eight curves to the space.
}{
\spadpaste{closedCurve(space,[[0,30,20], [0,30,30], [0,40,30],
[0,40,100], [0,30,100],[0,30,110], [0,60,110], [0,60,100],
[0,50,100], [0,50,30], [0,60,30], [0,60,20]]) \bound{curve1}
\free{space}}
}
\xctc{
}{
\spadpaste{closedCurve(space,[[80,0,30], [80,0,100], [70,0,110],
[40,0,110], [30,0,100], [30,0,90], [40,0,90], [40,0,95],
[45,0,100], [65,0,100], [70,0,95], [70,0,35]]) \bound{curve2}
\free{space}}
}
\xctc{

\subsubsection{Cube Example}

```

As a second example of the use of primitives, we generate a cube using a polygon mesh.

It is important to use a consistent orientation of the polygons for correct generation of \threedim{} objects.

```

\xtc{
Again start with an empty three-space object.
}{
\spadpaste{spaceC := create3Space()\$(ThreeSpace DFLOAT) \bound{spaceC}}
}
\xtc{
For convenience,
give \axiomType{DoubleFloat} values \axiom{+1} and \axiom{-1} names.
}{
\spadpaste{x: DFLOAT := 1 \bound{x}}
}
\xtc{
}{
\spadpaste{y: DFLOAT := -1 \bound{y}}
}
\xtc{
Define the vertices of the cube.
}{
\spadpaste{a := point [x,x,y,1::DFLOAT]\$(Point DFLOAT) \bound{a}
\free{x y}}
}
\xtc{
}{
\spadpaste{b := point [y,x,y,4::DFLOAT]\$(Point DFLOAT) \bound{b}
\free{x y}}
}
\xtc{
}{
\spadpaste{c := point [y,x,x,8::DFLOAT]\$(Point DFLOAT) \bound{c}
\free{x y}}
}
\xtc{
}{
\spadpaste{d := point [x,x,x,12::DFLOAT]\$(Point DFLOAT) \bound{d}
\free{x y}}
}
\xtc{
}{

11.0.141 Coordinate System Transformations

(ug07.ht)+≡

```
\begin{page}{ugGraphCoordPage}{7.2.7. Coordinate System Transformations}
\beginscroll
```

The `\axiomType{CoordinateSystems}` package provides coordinate transformation functions that map a given data point from the coordinate system specified into the Cartesian coordinate system. The default coordinate system, given a triplet `\axiom{(f(u,v), u, v)}`, assumes that `\axiom{z = f(u, v)}`, `\axiom{x = u}` and `\axiom{y = v}`, that is, reads the coordinates in `\axiom{(z, x, y)}` order.

```
\xtc{
}{
\spadpaste{m(u:DFLOAT,v:DFLOAT):DFLOAT == u**2 \bound{m}}
}
%
\psXtc{
Graph plotted in default coordinate system.
}{
\graphpaste{draw(m,0..3,0..5) \free{m}}
}{
\epsffile[0 0 295 295]{../ps/defcoord.ps}
}
```

The `\axiom{z}` coordinate comes first since the first argument of the `\axiomFun{draw}` command gives its values. In general, the coordinate systems Axiom provides, or any that you make up, must provide a map to an `\axiom{(x, y, z)}` triplet in order to be compatible with the `\axiomFunFrom{coordinates}{DrawOption}` `\axiomType{DrawOption}`. Here is an example.

```
\xtc{
Define the identity function.
}{
\spadpaste{cartesian(point:Point DFLOAT):Point DFLOAT == point
\bound{cart}}
}
\psXtc{
Pass \axiom{cartesian} as the \axiomFunFrom{coordinates}{DrawOption}
parameter to the \axiomFun{draw} command.
}{
\graphpaste{draw(m,0..3,0..5,coordinates==cartesian) \free{m cart}}
}{
\epsffile[0 0 295 295]{../ps/cartcoord.ps}
}
```

```
}
%
```

What happened? The option `\tt coordinates == cartesian` directs Axiom to treat the dependent variable `\axiom{m}` defined by `\texht{$m=u^2$}``{m=u**2}` as the `\axiom{x}` coordinate. Thus the triplet of values `\axiom{(m, u, v)}` is transformed to coordinates `\axiom{(x, y, z)}` and so we get the graph of `\texht{$x=y^2$}``{x=y**2}`.

Here is another example.

The `\axiomFunFrom{cylindrical}{CoordinateSystems}` transform takes input of the form `\axiom{(w,u,v)}`, interprets it in the order `\texht{(r, θ, z)}``{(\axiom{r}, \axiom{theta}, \axiom{z})}` and maps it to the Cartesian coordinates `\texht{$x=r\cos(\theta)$, $y=r\sin(\theta)$, $z=z$}``{\axiom{x} = r * cos(theta), \axiom{y} = r * sin(theta), \axiom{z} = z}` in which `\texht{r}``{\axiom{r}}` is the radius, `\texht{θ}``{\axiom{theta}}` is the angle and `\texht{z}``{\axiom{z}}` is the z-coordinate.

```
\xctc{
```

An example using the `\axiomFunFrom{cylindrical}{CoordinateSystems}` coordinates for the constant `\axiom{r} = 3`.

```
{
\spadpaste{f(u:DFLOAT,v:DFLOAT):DFLOAT == 3 \bound{f}}
}
\psXtc{
Graph plotted in cylindrical coordinates.
}{
\graphpaste{draw(f,0..\%pi,0..6,coordinates==cylindrical) \free{f}}
}{
\epsffile[0 0 295 295]{../ps/cylcoord.ps}
}
```

Suppose you would like to specify `\smath{z}` as a function of `\smath{r}` and `\texht{θ}``{\axiom{theta}}` instead of just `\smath{r}`? Well, you still can use the `\axiomFun{cylindrical}` Axiom transformation but we have to reorder the triplet before passing it to the transformation.

```
\xctc{
```

First, let's create a point to work with and call it `\axiom{pt}` with some color `\axiom{col}`.

```
{
\spadpaste{col := 5 \bound{c}}
}
```

```

\xtc{
}{
\spadpaste{pt := point[1,2,3,col]\$(Point DFLOAT) \free{c} \bound{pt}}
}
The reordering you want is
\texht{$(z,r, \theta)$}\{\axiom{(z,r,theta)}\} to
\texht{$(r, \theta,z)$}\{\axiom{(r,theta,z)}\}
so that the first element is moved to the third element, while the second
and third elements move forward and the color element does not change.
\xtc{
Define a function \userfun{reorder} to reorder the point elements.
}{
\spadpaste{
reorder(p:Point DFLOAT):Point DFLOAT == point[p.2, p.3, p.1, p.4]
\bound{freo}}
}
\xtc{
The function moves the second and third elements
forward but the color does not change.
}{
\spadpaste{reorder pt \free{pt freo}}
}
\xtc{
The function \userfun{newmap} converts our reordered version of
the cylindrical coordinate system to the standard
\texht{$(x,y,z)$}\{\axiom{(x,y,z)}\} Cartesian system.
}{
\spadpaste{
newmap(pt:Point DFLOAT):Point DFLOAT == cylindrical(reorder pt)
\free{freo} \bound{fnewmap}}
}
\xtc{
}{
\spadpaste{newmap pt \free{fnewmap pt} \bound{new}}
}
%
\psXtc{
Graph the same function \axiom{f} using the coordinate mapping
of the function \axiom{newmap}, so it is now interpreted as
\texht{z=3}\{\axiom{z = 3}\}:
}{
\graphpaste{draw(f,0..3,0..2*\%pi,coordinates==newmap) \free{f new}}
}{
\epsffile[0 0 295 295]{../ps/newmap.ps}
}

```

```

11.0.143 Three-Dimensional Control-Panel

<ug07.ht>+≡

```
\begin{page}{ugGraphThreeDControlPage}
{7.2.9. Three-Dimensional Control-Panel}
\beginscroll
```

Once you have created a viewport, move your mouse to the viewport and click with your left mouse button. This displays a control-panel on the side of the viewport that is closest to where you clicked.

```
\subsubsection{Transformations}
```

We recommend you first select the `{\bf Bounds}` button while executing transformations since the bounding box displayed indicates the object's position as it changes.

```
%
```

```
\indent{0}
```

```
\beginitems
```

```
%
```

```
\item[Rotate:] A rotation transformation occurs by clicking the mouse
within the {\bf Rotate} window in the upper left corner of the
control-panel.
```

The rotation is computed in spherical coordinates, using the horizontal mouse position to increment or decrement the value of the longitudinal angle `\texht{θ}``{\axiom{theta}}` within the range of 0 to `\texht{2π}``{2*pi}` and the vertical mouse position to increment or decrement the value of the latitudinal angle `\texht{ϕ}``{\axiom{phi}}` within the range of `\texht{-π}``{pi}` to `\texht{π}``{pi}`.

The active mode of rotation is displayed in green on a color monitor or in clear text on a black and white monitor, while the inactive mode is displayed in red for color display or a mottled pattern for black and white.

```
%
```

```
\indent{0}
```

```
\beginitems
```

```
\item[origin:] The {\bf origin} button indicates that the rotation is
to occur with respect to the origin of the viewing space, that is
indicated by the axes.
```

```
\item[object:] The {\bf object} button indicates that the
rotation is to occur with respect to the center of volume of the object,
independent of the axes' origin position.
```

```
\enditems
```

```
\indent{0}
```

```

%
\item[Scale:] A scaling transformation occurs by clicking the mouse
within the {\bf Scale} window in the upper center of the
control-panel, containing a zoom arrow.
The axes along which the scaling is to occur are indicated by
selecting the appropriate button above the zoom arrow window.
The selected axes are displayed in green on a color monitor or in
clear text on a black and white monitor, while the unselected axes
are displayed in red for a color display or a mottled pattern for
black and white.
%
\indent{0}
\beginitems
%
\item[uniform:] Uniform scaling along the {\tt x}, {\tt y}
and {\tt z} axes occurs when all the axes buttons are selected.

\item[non-uniform:] If any of the axes buttons are not selected,
non-uniform scaling occurs, that is, scaling occurs only in the
direction of the axes that are selected.
\enditems
\indent{0}

\item[Translate:] Translation occurs by indicating with the mouse in
the {\bf Translate} window the direction you want the graph to move.
This window is located in the upper right corner of the control-panel
and contains a potentiometer with crossed arrows pointing up, down,
left and right. Along the top of the {\bf Translate} window are three
buttons ({\bf XY}, {\bf XZ}, and {\bf YZ}) indicating the three
orthographic projection planes. Each orientates the group as a view
into that plane. Any translation of the graph occurs only along this
plane.
\enditems
\indent{0}

\subsubsection{Messages}

The window directly below the potentiometer windows for
transformations is used to display system messages relating to the
viewport, the control-panel and the current graph displaying status.

\subsubsection{Colormap}

Directly below the message window is the colormap range indicator
window. The Axiom Colormap shows a sampling of the spectrum from
which hues can be drawn to represent the colors of a surface. The

```

Colormap is composed of five shades for each of the hues along this spectrum. By moving the markers above and below the Colormap, the range of hues that are used to color the existing surface are set. The bottom marker shows the hue for the low end of the color range and the top marker shows the hue for the upper end of the range. Setting the bottom and top markers at the same hue results in monochromatic smooth shading of the graph when {\bf Smooth} mode is selected. At each end of the Colormap are {\bf +} and {\bf -} buttons. When clicked on, these increment or decrement the top or bottom marker.

\subsubsection{Buttons}

Below the Colormap window and to the left are located various buttons that determine the characteristics of a graph. The buttons along the bottom and right hand side all have special meanings; the remaining buttons in the first row indicate the mode or style used to display the graph.

The second row are toggles that turn on or off a property of the graph.

On a color monitor, the property is on if green (clear text, on a monochrome monitor) and off if red (mottled pattern, on a monochrome monitor).

Here is a list of their functions.

%

\indent{0}

\beginitems

\item[Wire] displays surface and tube plots as a wireframe image in a single color (blue) with no hidden surfaces removed, or displays space curve plots in colors based upon their parametric variables. This is the fastest mode for displaying a graph. This is very useful when you want to find a good orientation of your graph.

\item[Solid] displays the graph with hidden surfaces removed, drawing each polygon beginning with the furthest from the viewer.

The edges of the polygons are displayed in the hues specified by the range in the Colormap window.

%

\item[Shade] displays the graph with hidden surfaces removed and with the polygons shaded, drawing each polygon beginning with the furthest from the viewer. Polygons are shaded in the hues specified by the range in the Colormap window using the Phong illumination model.

%

\item[Smooth] displays the graph using a

renderer that computes the graph one line at a time.

The location and color of the graph at each visible point on the screen are determined and displayed using the Phong illumination model.

Smooth shading is done in one of two ways, depending on the range selected in the colormap window and the number of colors available from the hardware and/or window manager.

When the top and bottom markers of the colormap range are set to different hues, the graph is rendered by dithering between the transitions in color hue.

When the top and bottom markers of the colormap range are set to the same hue, the graph is rendered using the Phong smooth shading model.

However, if enough colors cannot be allocated for this purpose, the renderer reverts to the color dithering method until a sufficient color supply is available.

For this reason, it may not be possible to render multiple Phong smooth shaded graphs at the same time on some systems.

`\item[Bounds]` encloses the entire volume of the viewgraph within a bounding box, or removes the box if previously selected. The region that encloses the entire volume of the viewport graph is displayed.

`\item[Axes]` displays Cartesian coordinate axes of the space, or turns them off if previously selected.

`\item[Outline]` causes quadrilateral polygons forming the graph surface to be outlined in black when the graph is displayed in `{\bf Shade}` mode.

`\item[BW]` converts a color viewport to black and white, or vice-versa. When this button is selected the control-panel and viewport switch to an immutable colormap composed of a range of grey scale patterns or tiles that are used wherever shading is necessary.

`\item[Light]` takes you to a control-panel described below.
%

`\item[ViewVolume]` takes you to another control-panel as described below.

`\item[Save]` creates a menu of the possible file types that can be written using the control-panel. The `{\bf Exit}` button leaves the save menu. The `{\bf Pixmap}` button writes an Axiom pixmap of the current viewport contents. The file is called `{\bf axiom3D.pixmap}` and is located in the directory from which Axiom or `{\bf viewalone}` was started. The `{\bf PS}` button writes the current viewport contents to PostScript output rather than to the viewport window. By default

the file is called {\bf axiom3D.ps}; however, if a file name is specified in the user's {\bf .Xdefaults} file it is used. The file is placed in the directory from which the Axiom or {\bf viewalone} session was begun. See also the `\axiomFunFrom{write}{ThreeDimensionalViewport}` function.

```
\item[Reset] returns the object transformation
characteristics back to their initial states.
%
\item[Hide] causes the control-panel for the
corresponding viewport to disappear from the screen.
%
\item[Quit] queries whether the current viewport
session should be terminated.
\enditems
\indent{0}
```

`\subsubsection{Light}`

The {\bf Light} button changes the control-panel into the {\bf Lighting Control-Panel}. At the top of this panel, the three axes are shown with the same orientation as the object. A light vector from the origin of the axes shows the current position of the light source relative to the object. At the bottom of the panel is an {\bf Abort} button that cancels any changes to the lighting that were made, and a {\bf Return} button that carries out the current set of lighting changes on the graph.

```
%
\indent{0}
\beginitems
%
\item[XY:] The {\bf XY} lighting axes window is below the
{\bf Lighting Control-Panel} title and to the left.
This changes the light vector within the {\bf XY} view plane.
%
```

```
\item[Z:] The {\bf Z} lighting axis window is below the
{\bf Lighting Control-Panel} title and in the center. This
changes the {\bf Z}
location of the light vector.
%
```

```
\item[Intensity:]
Below the {\bf Lighting Control-Panel} title
and to the right is the light intensity meter.
Moving the intensity indicator down decreases the amount of
light emitted from the light source.
When the indicator is at the top of the meter the light source is
```

emitting at 100\% intensity.

At the bottom of the meter the light source is emitting at a level slightly above ambient lighting.

\enditems

\indent{0}

\subsubsection{View Volume}

The {\bf View Volume} button changes the control-panel into the {\bf Viewing Volume Panel}.

At the bottom of the viewing panel is an {\bf Abort} button that cancels any changes to the viewing volume that were made and a {\bf Return} button that carries out the current set of viewing changes to the graph.

\indent{0}

\beginitems

\item[Eye Reference:] At the top of this panel is the {\bf Eye Reference} window. It shows a planar projection of the viewing pyramid from the eye of the viewer relative to the location of the object. This has a bounding region represented by the rectangle on the left. Below the object rectangle is the {\bf Hither} window. By moving the slider in this window the hither clipping plane sets the front of the view volume. As a result of this depth clipping all points of the object closer to the eye than this hither plane are not shown. The {\bf Eye Distance} slider to the right of the {\bf Hither} slider is used to change the degree of perspective in the image.

\item[Clip Volume:] The {\bf Clip Volume} window is at the bottom of the {\bf Viewing Volume Panel}. On the right is a {\bf Settings} menu. In this menu are buttons to select viewing attributes. Selecting the {\bf Perspective} button computes the image using perspective projection. The {\bf Show Region} button indicates whether the clipping region of the volume is to be drawn in the viewport and the {\bf Clipping On} button shows whether the view volume clipping is to be in effect when the image is drawn. The left side of the {\bf Clip Volume} window shows the clipping boundary of the graph. Moving the knobs along the {\bf X}, {\bf Y}, and {\bf Z} sliders adjusts the volume of the clipping region accordingly.

11.0.144 Operations for Three-Dimensional Graphics

<ug07.ht>+≡

```
\begin{page}{ugGraphThreeDopsPage}
{7.2.10. Operations for Three-Dimensional Graphics}
\beginscroll
```

Here is a summary of useful Axiom operations for `\threedim{}` graphics. Each operation name is followed by a list of arguments. Each argument is written as a variable informally named according to the type of the argument (for example, `{\it integer}`). If appropriate, a default value for an argument is given in parentheses immediately following the name.

```
%
\texht{\bgroup\hbadness = 10001\sloppy}{ }
\indent{0}
\beginitems
%
\item[\axiomFun{adaptive3D?}]{\funArgs{ }
tests whether space curves are to be plotted
according to the
adaptive refinement algorithm.

%
\item[\axiomFun{axes}]{\funArgs{viewport, string\argDef{"on"}}
turns the axes on and off.

%
\item[\axiomFun{close}]{\funArgs{viewport}
closes the viewport.

%
\item[\axiomFun{colorDef}]{\funArgs{viewport,
\subscriptIt{color}{1}\argDef{1}, \subscriptIt{color}{2}\argDef{27}}
sets the colormap
range to be from
\subscriptIt{color}{1} to \subscriptIt{color}{2}.

%
\item[\axiomFun{controlPanel}]{\funArgs{viewport, string\argDef{"off"}}
declares whether the
control-panel for the viewport is to be displayed or not.

%
\item[\axiomFun{diagonals}]{\funArgs{viewport, string\argDef{"off"}}
```

declares whether the
polygon outline includes the diagonals or not.

%
\item[\axiomFun{drawStyle}]\funArgs{viewport, style}
selects which of four drawing styles
are used: {\tt "wireMesh", "solid", "shade",} or {\tt "smooth".}

%
\item[\axiomFun{eyeDistance}]\funArgs{viewport,float\argDef{500}}
sets the distance of the eye from the origin of the object
for use in the \axiomFunFrom{perspective}{ThreeDimensionalViewport}.

%
\item[\axiomFun{key}]\funArgs{viewport}
returns the operating
system process ID number for the viewport.

%
\item[\axiomFun{lighting}]\funArgs{viewport,
\subscriptText{float}{x}\argDef{-0.5},
\subscriptText{float}{y}\argDef{0.5}, \subscriptText{float}{z}\argDef{0.5}}
sets the Cartesian
coordinates of the light source.

%
\item[\axiomFun{modifyPointData}]\funArgs{viewport,integer,point}
replaces the coordinates of the point with
the index {\it integer} with {\it point}.

%
\item[\axiomFun{move}]\funArgs{viewport,
\subscriptText{integer}{x}\argDef{viewPosDefault},
\subscriptText{integer}{y}\argDef{viewPosDefault}}
moves the upper
left-hand corner of the viewport to screen position
\allowbreak
({\small \subscriptText{integer}{x}, \subscriptText{integer}{y}}).

%
\item[\axiomFun{options}]\funArgs{viewport}
returns a list of all current draw options.

%
\item[\axiomFun{outlineRender}]\funArgs{viewport, string\argDef{"off"}}
turns polygon outlining

off or on when drawing in {\tt "shade"} mode.

```
%
\item[\axiomFun{perspective}]\funArgs{viewport, string\argDef{"on"}}
turns perspective
viewing on and off.
```

```
%
\item[\axiomFun{reset}]\funArgs{viewport}
resets the attributes of a viewport to their
initial settings.
```

```
%
\item[\axiomFun{resize}]\funArgs{viewport,
\subscriptText{integer}{width} \argDef{viewSizeDefault},
\subscriptText{integer}{height} \argDef{viewSizeDefault}}
resets the width and height
values for a viewport.
```

```
%
\item[\axiomFun{rotate}]\funArgs{viewport,
\subscriptText{number}{\texht{$\theta$}}{\axiom{theta}}}
\argDef{viewThetaDefault},
\subscriptText{number}{\texht{$\phi$}}{\axiom{phi}}}
\argDef{viewPhiDefault}}
rotates the viewport by rotation angles for longitude
({\it \texht{$\theta$}}{\axiom{theta}}) and
latitude ({\it \texht{$\phi$}}{\axiom{phi}}).
Angles designate radians if given as floats, or degrees if given
as integers.
```

```
%
\item[\axiomFun{setAdaptive3D}]\funArgs{boolean\argDef{true}}
sets whether space curves are to be plotted
according to the adaptive
refinement algorithm.
```

```
%
\item[\axiomFun{setMaxPoints3D}]\funArgs{integer\argDef{1000}}
sets the default maximum number of possible
points to be used when constructing a \threedim{} space curve.
```

```
%
\item[\axiomFun{setMinPoints3D}]\funArgs{integer\argDef{49}}
sets the default minimum number of possible
points to be used when constructing a \threedim{} space curve.
```

```

%
\item[\axiomFun{setScreenResolution3D}]\funArgs{integer\argDef{500}}
sets the default screen resolution constant
used in setting the computation limit of adaptively
generated \threedim{} space curve plots.

%
\item[\axiomFun{showRegion}]\funArgs{viewport, string\argDef{"off"}}
declares whether the bounding
box of a graph is shown or not.
%
\item[\axiomFun{subspace}]\funArgs{viewport}
returns the space component.
%
\item[\axiomFun{subspace}]\funArgs{viewport, subspace}
resets the space component
to {\it subspace}.

%
\item[\axiomFun{title}]\funArgs{viewport, string}
gives the viewport the
title {\it string}.

%
\item[\axiomFun{translate}]\funArgs{viewport,
\subscriptText{float}{x}\argDef{viewDeltaXDefault},
\subscriptText{float}{y}\argDef{viewDeltaYDefault}}
translates the object horizontally and vertically
relative to the center of the viewport.

%
\item[\axiomFun{intensity}]\funArgs{viewport,float\argDef{1.0}}
resets the intensity {\it I} of the light source,
\texht{$0 \le I \le 1.$}\{\it 0 \le I \le 1.\}

%
\item[\axiomFun{tubePointsDefault}]\funArgs{\optArg{integer\argDef{6}}}}
sets or indicates the default number of
vertices defining the polygon that is used to create a tube around
a space curve.

%
\item[\axiomFun{tubeRadiusDefault}]\funArgs{\optArg{float\argDef{0.5}}}}
sets or indicates the default radius of
the tube that encircles a space curve.

```

```

%
\item[\axiomFun{var1StepsDefault}]\funArgs{\optArg{integer\argDef{27}}}{
sets or indicates the default number of
increments into which the grid defining a surface plot is subdivided with
respect to the first parameter declared in the surface function.

%
\item[\axiomFun{var2StepsDefault}]\funArgs{\optArg{integer\argDef{27}}}{
sets or indicates the default number of
increments into which the grid defining a surface plot is subdivided with
respect to the second parameter declared in the surface function.

%
\item[\axiomFun{viewDefaults}]\funArgs{{\tt []}\subscriptText{integer}{%
point}, \subscriptText{integer}{line}, \subscriptText{integer}{axes},
\subscriptText{integer}{units}, \subscriptText{float}{point},
\allowbreak\subscriptText{list}{position},
\subscriptText{list}{size}{\tt []}}
resets the default settings for the
point color, line color, axes color, units color, point size,
viewport upper left-hand corner position, and the viewport size.

%
\item[\axiomFun{viewDeltaXDefault}]\funArgs{\optArg{float\argDef{0}}}{
resets the default horizontal offset
from the center of the viewport, or returns the
current default offset if no argument is given.

%
\item[\axiomFun{viewDeltaYDefault}]\funArgs{\optArg{float\argDef{0}}}{
resets the default vertical offset
from the center of the viewport, or returns the
current default offset if no argument is given.

%
\item[\axiomFun{viewPhiDefault}]\funArgs{\optArg{float
\argDef{-\texht{$\pi$}}{\it pi}/4}}{
resets the default latitudinal view angle,
or returns the current default angle if no argument is given.
\texht{$\pi$}{\it pi} is set to this value.

%
\item[\axiomFun{viewpoint}]\funArgs{viewport, \subscriptText{float}{x},
\subscriptText{float}{y}, \subscriptText{float}{z}}{
sets the viewing position in Cartesian coordinates.

```

```

%
\item[\axiomFun{viewpoint}]\funArgs{viewport,
\subscriptText{Float}{\texht{$\theta$}\axiom{theta}},
\subscriptText{Float}{\texht{$\phi$}\axiom{phi}}}
sets the viewing position in spherical coordinates.

%
\item[\axiomFun{viewpoint}]\funArgs{viewport,
\subscriptText{Float}{\texht{$\theta$}\axiom{theta}},
\subscriptText{Float}{\texht{$\phi$}\axiom{phi}},
\subscriptText{Float}{scaleFactor},
\subscriptText{Float}{xOffset}, \subscriptText{Float}{yOffset}}
sets the viewing position in spherical coordinates,
the scale factor, and offsets.
\texht{$\theta$}\it theta} (longitude) and
\texht{$\phi$}\it phi} (latitude) are in radians.

%
\item[\axiomFun{viewPosDefault}]\funArgs{\optArg{list\argDef{[0,0]}}}
sets or indicates the position of the upper
left-hand corner of a \twodim{} viewport, relative to the display root
window (the upper left-hand corner of the display is \axiom{[0, 0]}).

%
\item[\axiomFun{viewSizeDefault}]\funArgs{\optArg{list\argDef{[400,400]}}}
sets or indicates the width and height dimensions
of a viewport.

%
\item[\axiomFun{viewThetaDefault}]
\funArgs{\optArg{float\argDef{\texht{$\pi$}\it pi}/4}}
resets the default longitudinal view angle,
or returns the current default angle if no argument is given.
When a parameter is specified, the default longitudinal view angle
\texht{$\theta$}\it theta} is set to this value.

%
\item[\axiomFun{viewWriteAvailable}]
\funArgs{\optArg{list\argDef{["pixmap",
"bitmap", "postscript", "image"]}}}
indicates the possible file types
that can be created with the
\axiomFunFrom{write}{ThreeDimensionalViewport} function.

%

```

```

\item[\axiomFun{viewWriteDefault}]\funArgs{\optArg{list\argDef{[]}}}{
sets or indicates the default types of files
that are created in addition to the {\bf data} file when a
\axiomFunFrom{write}{ThreeDimensionalViewport} command
is executed on a viewport.

%
\item[\axiomFun{viewScaleDefault}]\funArgs{\optArg{float}}{
sets the default scaling factor, or returns
the current factor if no argument is given.

%
\item[\axiomFun{write}]\funArgs{viewport, directory, \optArg{option}}{
writes the file {\bf data} for {\it viewport}
in the directory {\it directory}.
An optional third argument specifies a file type (one of {\tt
pixmap}, {\tt bitmap}, {\tt postscript}, or {\tt image}), or a
list of file types.
An additional file is written for each file type listed.

%
\item[\axiomFun{scale}]\funArgs{viewport, float\argDef{2.5}}{
specifies the scaling factor.

11.0.145 Customization using .Xdefaults

(ug07.ht)+≡

```
\begin{page}{ugXdefaultsPage}{7.2.11. Customization using .Xdefaults}
\beginscroll
```

Both the `\twodim{}` and `\threedim{}` drawing facilities consult the `{\bf .Xdefaults}` file for various defaults. The list of defaults that are recognized by the graphing routines is discussed in this section.

These defaults are preceded by `{\tt Axiom.3D.}` for `\threedim{}` viewport defaults, `{\tt Axiom.2D.}` for `\twodim{}` viewport defaults, or `{\tt Axiom*}` (no dot) for those defaults that are acceptable to either viewport type.

```
%
\indent{0}
\beginitems
%
\item[{\tt Axiom*buttonFont:\ \it font}] \ \newline
This indicates which
font type is used for the button text on the control-panel.
\xdefault{Rom11}
%
\item[{\tt Axiom.2D.graphFont:\ \it font}] \quad (2D only) \newline
This indicates
which font type is used for displaying the graph numbers and
slots in the {\bf Graphs} section of the \twodim{} control-panel.
\xdefault{Rom22}
%
\item[{\tt Axiom.3D.headerFont:\ \it font}] \ \newline
This indicates which
font type is used for the axes labels and potentiometer
header names on \threedim{} viewport windows.
This is also used for \twodim{} control-panels for indicating
which font type is used for potentiometer header names and
multiple graph title headers.
%for example, {\tt Axiom.2D.headerFont: 8x13}.
\xdefault{Itl14}
%
\item[{\tt Axiom*inverse:\ \it switch}] \ \newline
This indicates whether the
background color is to be inverted from white to black.
If {\tt on}, the graph viewports use black as the background
color.
If {\tt off} or no declaration is made, the graph viewports use a
```

```

white background.
\xdefault{off}
%
\item[{\tt Axiom.3D.lightingFont:\ \it font}] \quad (3D only) \newline
This indicates which font type is used for the {\bf x},
{\bf y}, and {\bf z} labels of the two lighting axes potentiometers,
and for the {\bf Intensity} title on the lighting control-panel.
\xdefault{Rom10}
%
\item[
{\tt Axiom.2D.messageFont, Axiom.3D.messageFont:\ \it font}] \ \newline
These indicate the font type
to be used for the text in the control-panel message window.
\xdefault{Rom14}
%
\item[{\tt Axiom*monochrome:\ \it switch}] \ \newline
This indicates whether the
graph viewports are to be displayed as if the monitor is black and
white, that is, a 1 bit plane.
If {\tt on} is specified, the viewport display is black and white.
If {\tt off} is specified, or no declaration for this default is
given, the viewports are displayed in the normal fashion for the
monitor in use.
\xdefault{off}
%
\item[{\tt Axiom.2D.postScript:\ \it filename}] \ \newline
This specifies
the name of the file that is generated when a 2D PostScript graph
is saved.
\xdefault{axiom2D.ps}
%
\item[{\tt Axiom.3D.postScript:\ \it filename}] \ \newline
This specifies
the name of the file that is generated when a 3D PostScript graph
is saved.
\xdefault{axiom3D.ps}
%
\item[{\tt Axiom*titleFont \it font}] \ \newline
This
indicates which font type is used
for the title text and, for \threedim{} graphs,
in the lighting and viewing-volume control-panel windows.
\xdefault{Rom14}
%
\item[{\tt Axiom.2D.unitFont:\ \it font}] \quad (2D only) \newline
This indicates

```

```

which font type is used for displaying the unit labels on
\twodim{} viewport graphs.
\xddefault{6x10}
%
\item[{\tt Axiom.3D.volumeFont:\ \it font}] \quad (3D only) \newline
This indicates which font type is used for the {\bf x},
{\bf y}, and {\bf z} labels of the clipping region sliders; for the
{\bf Perspective}, {\bf Show Region}, and {\bf Clipping On} buttons under
{\bf Settings}, and above the windows for the {\bf Hither} and
{\bf Eye Distance} sliders in the {\bf Viewing Volume Panel} of the
\threedim{} control-panel.

```

```
\beginscroll
```

```
Axiom provides two basic floating-point types: \axiomType{Float} and
\axiomType{DoubleFloat}. This section describes how to use numerical
operations defined on these types and the related complex types.
```

```
As we mentioned in \downlink{‘‘An Overview of Axiom’’}{ugIntroPage} in
Chapter 1\ignore{ugIntro}, the \axiomType{Float} type is
a software implementation of floating-point numbers in which the
exponent and the significand may have any number of digits. See
\downlink{‘Float’}{FloatXmpPage}\ignore{Float} for detailed
information about this domain. The \axiomType{DoubleFloat} (see
\downlink{‘DoubleFloat’}{DoubleFloatXmpPage}\ignore{DoubleFloat}) is
usually a hardware implementation of floating point numbers,
corresponding to machine double precision. The types
\axiomType{Complex Float} and \axiomType{Complex DoubleFloat} are the
corresponding software implementations of complex floating-point
```

numbers. In this section the term {\it floating-point type} means any of these four types.

The floating-point types implement the basic elementary functions. These include (where \axiomSyntax{\\$} means

```
\axiomType{DoubleFloat},
\axiomType{Float},
\axiomType{Complex DoubleFloat}, or
\axiomType{Complex Float}):
```

```
\noindent
\axiomFun{exp}, \axiomFun{log}: \axiom{\$ -> \$} \newline
\axiomFun{sin}, \axiomFun{cos}, \axiomFun{tan}, \axiomFun{cot},
\axiomFun{sec}, \axiomFun{csc}: \axiom{\$ -> \$} \newline
\axiomFun{sin}, \axiomFun{cos}, \axiomFun{tan}, \axiomFun{cot},
\axiomFun{sec}, \axiomFun{csc}: \axiom{\$ -> \$} \newline
\axiomFun{asin}, \axiomFun{acos}, \axiomFun{atan}, \axiomFun{acot},
\axiomFun{asec}, \axiomFun{acsc}: \axiom{\$ -> \$} \newline
\axiomFun{sinh}, \axiomFun{cosh}, \axiomFun{tanh}, \axiomFun{coth},
\axiomFun{sech}, \axiomFun{csch}: \axiom{\$ -> \$} \newline
\axiomFun{asinh}, \axiomFun{acosh}, \axiomFun{atanh}, \axiomFun{acoth},
\axiomFun{asech}, \axiomFun{acsch}: \axiom{\$ -> \$} \newline
\axiomFun{pi}: \axiom{() -> \$} \newline
\axiomFun{sqrt}: \axiom{\$ -> \$} \newline
\axiomFun{nthRoot}: \axiom{(\$, Integer) -> \$} \newline
\axiomFunFrom{**}{Float}: \axiom{(\$, Fraction Integer) -> \$} \newline
\axiomFunFrom{**}{Float}: \axiom{(\$,\$) -> \$} \newline
```

The handling of roots depends on whether the floating-point type is real or complex: for the real floating-point types, \axiomType{DoubleFloat} and \axiomType{Float}, if a real root exists the one with the same sign as the radicand is returned; for the complex floating-point types, the principal value is returned. Also, for real floating-point types the inverse functions produce errors if the results are not real. This includes cases such as \axiom{asin(1.2)}, \axiom{log(-3.2)}, \axiom{sqrt(-1.1)}.

```
%
\xtc{
The default floating-point type is \axiomType{Float} so to evaluate
functions using \axiomType{Float} or \axiomType{Complex Float}, just
use normal decimal notation.
}{
\spadpaste{exp(3.1)}
}
\xtc{
```

```

}{
\spadpaste{exp(3.1 + 4.5 * \%i)}
}
\xtc{
To evaluate functions using \axiomType{DoubleFloat}
or \axiomType{Complex DoubleFloat},
a declaration or conversion is required.
}{
\spadpaste{r: DFLOAT := 3.1; t: DFLOAT := 4.5; exp(r + t*\%i)}
}
\xtc{
}{
\spadpaste{exp(3.1::DFLOAT + 4.5::DFLOAT * \%i)}
}

```

A number of special functions are provided by the package `\axiomType{DoubleFloatSpecialFunctions}` for the machine-precision floating-point types. The special functions provided are listed below, where `\axiom{F}` stands for the types `\axiomType{DoubleFloat}` and `\axiomType{Complex DoubleFloat}`. The real versions of the functions yield an error if the result is not real.

```

\noindent
\axiomFun{Gamma}: \axiom{F -> F}\hfill\newline
\axiom{Gamma(z)} is the Euler gamma function,
  \texht{$\Gamma(z)$}\{\axiom{Gamma(z)}\},
  defined by
  \texht{
\narrowDisplay{\Gamma(z) = \int_{0}^{\infty} t^{z-1} e^{-t} dt.}%
  }{
\newline
\centerline{{
\axiom{Gamma(z) = integrate(t**(z-1)*exp(-t), t=0..\%infinity).}}}
}

\noindent
\axiomFun{Beta}: \axiom{F -> F}\hfill\newline
  \axiom{Beta(u, v)} is the Euler Beta function,
  \texht{$B(u,v)$}\{\axiom{B(u,v)}\}, defined by
  \texht{\narrowDisplay{B(u,v) = \int_{0}^{1} t^{u-1} (1-t)^{v-1} dt.}%
  }{
\newline
\centerline{{
\axiom{Beta(u,v) = integrate(t**(u-1)*(1-t)**(v-1), t=0..1).}}}
}
  This is related to \texht{$\Gamma(z)$}\{\axiom{Gamma(z)}\} by

```

```

\text{\narrowDisplay{B(u,v) =
\frac{\Gamma(u) \Gamma(v)}{\Gamma(u + v)}}.%
}{
\newline
\centerline{{ \axiom{Beta(u,v) = Gamma(u)*Gamma(v)/Gamma(u + v)}}}
}%

\noindent
\axiomFun{logGamma}: \axiom{F -> F}\hfill\newline
\axiom{logGamma(z)} is the natural logarithm of
\text{\Gamma(z)}{\axiom{Gamma(z)}}.
This can often be computed even if
\text{\Gamma(z)}{\axiom{Gamma(z)}}
cannot.
%

\noindent
\axiomFun{digamma}: \axiom{F -> F}\hfill\newline
\axiom{digamma(z)}, also called \axiom{psi(z)},
is the function \text{\psi(z)}{\axiom{psi(z)}},
defined by \text{\narrowDisplay{\psi(z) = \Gamma'(z)/\Gamma(z)}}%
}{
\newline
\centerline{{ \axiom{psi(z) = Gamma'(z)/Gamma(z)}}}
}%

\noindent
\axiomFun{polygamma}:
\axiom{(NonNegativeInteger, F) -> F}\hfill\newline
\axiom{polygamma(n, z)} is the \eth{\axiom{n}} derivative of
\text{\psi(z)}{
\axiom{digamma(z)}}\text{, written } \psi^{(n)}(z){}.

\noindent
\axiomFun{besselJ}: \axiom{(F,F) -> F}\hfill\newline
\axiom{besselJ(v,z)} is the Bessel function of the first kind,
\text{J_{\nu}(z)}{\axiom{J(v,z)}}.
This function satisfies the differential equation
\text{\narrowDisplay{z^2 w''(z) + z w'(z) + (z^2 - \nu^2)w(z) = 0}}%
}{
\newline
\centerline{{ \axiom{z**2*w''(z) + z*w'(z) + (z**2-v**2)*w(z) = 0}}}
}%

\noindent
\axiomFun{besselY}: \axiom{(F,F) -> F}\hfill\newline

```

```

\axiom{bessely(v,z)} is the Bessel function of the second kind,
\texht{\$Y_{\nu}(z)\$}\{\axiom{Y(v,z)}\}.
This function satisfies the same differential equation as
\axiomFun{besselJ}.
The implementation simply uses the relation
\texht{\narrowDisplay{Y_{\nu}(z) =
\frac{J_{\nu}(z) \cos(\nu \pi) - J_{-\nu}(z)}{\sin(\nu \pi)}}}%
}{
\newline
\centerline{{\axiom{Y(v,z) =
(J(v,z)*cos(v*\%pi) - J(-v,z))/sin(v*\%pi)}}}
}%

\noindent
\axiomFun{besselI}: \axiom{(F,F) -> F}\hfill\newline
\axiom{besselI(v,z)} is the modified Bessel function of the first kind,
\texht{\$I_{\nu}(z)\$}\{\axiom{I(v,z)}\}.
This function satisfies the differential equation

A number of additional operations may be used to compute numerical values. These are special polynomial functions that can be evaluated for values in any commutative ring $\text{axiom}\{R\}$, and in particular for

values in any floating-point type. The following operations are provided by the package `\axiomType{OrthogonalPolynomialFunctions}`:

```

\noindent
\axiomFun{chebyshevT}:
\axiom{(NonNegativeInteger, R) -> R}\hbox{}\hfill\newline
  \axiom{chebyshevT(n,z)} is the \eth{\axiom{n}}
Chebyshev polynomial of the first
  kind, \texht{$T_n(z)$}\{\axiom{T[n](z)}\}. These are defined by
  \texht{\narrowDisplay{\frac{1-t z}{1-2 t z+t^2}} =
\sum_{n=0}^{\infty} T_n(z) t^n.}%
  }{
\newline
\centerline{{ \axiom{(1-t*z)/(1-2*t*z+t**2)} =
sum(T[n](z) *t**n, n = 0..).}}}
}%

\noindent
\axiomFun{chebyshevU}: \axiom{(NonNegativeInteger, R) -> R}
\hbox{}\hfill\newline
  \axiom{chebyshevU(n,z)} is the \eth{\axiom{n}}
Chebyshev polynomial of the second
  kind, \texht{$U_n(z)$}\{\axiom{U[n](z)}\}. These are defined by
  \texht{\narrowDisplay{\frac{1}{1-2 t z+t^2}} =
\sum_{n=0}^{\infty} U_n(z) t^n.}%
  }{
\newline
\centerline{{ \axiom{1/(1-2*t*z+t**2)} = sum(U[n](z) *t**n, n = 0..).}}}
}%

\noindent
\axiomFun{hermiteH}: \axiom{(NonNegativeInteger, R) -> R}
\hbox{}\hfill\newline
  \axiom{hermiteH(n,z)} is the \eth{\axiom{n}} Hermite polynomial,
  \texht{$H_n(z)$}\{\axiom{H[n](z)}\}.
  These are defined by
  \texht{\narrowDisplay{e^{2 t z - t^2}} =
\sum_{n=0}^{\infty} H_n(z) \frac{t^n}{n!}.}%
  }{
\newline
\centerline{{ \axiom{exp(2*t*z-t**2)} = sum(H[n](z)*t**n/n!, n = 0..).}}}
}%

\noindent
\axiomFun{laguerreL}: \axiom{(NonNegativeInteger, R) -> R}
\hbox{}\hfill\newline

```

```

\axiom{laguerreL(n,z)} is the \eth{\axiom{n}} Laguerre polynomial,
\texht{$L_n(z)$}\{\axiom{L[n](z)}\}.
These are defined by
\texht{\narrowDisplay{\frac{e^{-\frac{t}{z}(1-t)}}{(1-t)} =
\sum_{n=0}^{\infty} L_n(z) \frac{t^n}{n!}.}%
}{
\newline
\centerline{{ \axiom{exp(-t*z/(1-t))/(1-t) =
sum(L[n](z)*t**n/n!, n = 0..).}}}
}%

\noindent
\axiomFun{laguerreL}:
\axiom{(NonNegativeInteger, NonNegativeInteger, R) -> R}\hbox{}\hfill\newline
\axiom{laguerreL(m,n,z)} is the associated Laguerre polynomial,
\texht{$L^m_n(z)$}\{\axiom{L<m>[n](z)}\}.
This is the
\eth{\axiom{m}} derivative of \texht{$L_n(z)$}\{\axiom{L[n](z)}\}.

\noindent
\axiomFun{legendreP}:
\axiom{(NonNegativeInteger, R) -> R}\hbox{}\hfill\newline
\axiom{legendreP(n,z)} is the \eth{\axiom{n}} Legendre polynomial,
\texht{$P_n(z)$}\{\axiom{P[n](z)}\}. These are defined by
\texht{\narrowDisplay{
\frac{1}{\sqrt{1-2tz+t^2}} = \sum_{n=0}^{\infty} P_n(z) t^n.}%
}{
\newline
\centerline{{ \axiom{1/sqrt(1-2*z*t+t**2) =
sum(P[n](z)*t**n, n = 0..).}}}
}%

```

Drawing complex functions in Axiom is presently somewhat awkward compared to drawing real functions. It is necessary to use the `\axiomFun{draw}` operations that operate on functions rather than expressions.

```

\psXtc{
This is the complex exponential function\texht{ (rotated
interactively).}{.} When this is displayed in color, the height is
the value of the real part of the function and the color is the
imaginary part. Red indicates large negative imaginary values, green
indicates imaginary values near zero and blue/violet indicates large
positive imaginary values.
}{

```

```

\graphpaste{draw((x,y)--> real exp complex(x,y), -2..2,
-2*\%pi..2*\%pi, colorFunction ==
(x, y) --> imag exp complex(x,y),
title=="exp(x+\%i*y)", style=="smooth")}
}{
\epsffile[0 0 295 295]{../ps/compexp.ps}
}

\psXtc{
This is the complex arctangent function.
Again, the height is the real part of the function value but here
the color indicates the function value's phase.
The position of the branch cuts are clearly visible and one can
see that the function is real only for a real argument.
}{
\graphpaste{vp := draw((x,y) --> real atan complex(x,y),
-\%pi.. \%pi, - \%pi.. \%pi, colorFunction==
(x,y) --> argument atan complex(x,y),
title=="atan(x+\%i*y)", style=="shade"); rotate(vp,-160,-45); vp}
}{
\epsffile[0 0 295 295]{../ps/compatan.ps}
}

\psXtc{
This is the complex Gamma function.
}{
\graphpaste{draw((x,y) --> max(min(real Gamma complex(x,y),4),-4),
-\%pi.. \%pi, - \%pi.. \%pi, style=="shade", colorFunction ==
(x,y) --> argument Gamma complex(x,y),
title == "Gamma(x+\%i*y)", var1Steps == 50, var2Steps== 50)}
}{
\epsffile[0 0 295 295]{../ps/compgamma.ps}
}

\psXtc{
This shows the real Beta function near the origin.
}{
\graphpaste{draw(Beta(x,y)/100, x=-1.6..1.7, y = -1.6..1.7,
style=="shade", title=="Beta(x,y)", var1Steps==40, var2Steps==40)}
}{
\epsffile[0 0 295 295]{../ps/realbeta.ps}
}

\psXtc{
This is the Bessel function \texht{$J_{\alpha}(x)$}\{\axiom{J(alpha,x)}\}
for index \texht{$\alpha$}\{\axiom{alpha}\} in the range \axiom{-6.4} and

```

```

argument \texht{$x$}\axiom{x} in the range \axiom{2..14}.
}{
\graphpaste{draw((alpha,x) +-> min(max(besselJ(alpha, x+8), -6), 6),
-6..4, -6..6, title=="besselJ(alpha,x)", style=="shade",
var1Steps==40, var2Steps==40)}
}{
\epsffile[0 0 295 295]{../ps/bessel.ps}
}

\psXtc{
This is the modified Bessel function
\texht{$I_{\alpha}(x)$}\axiom{I(alpha,x)}
evaluated for various real values of the index
\texht{$\alpha$}\axiom{alpha}
and fixed argument \texht{$x = 5$}\axiom{x = 5}.
}{
\graphpaste{draw(besselI(alpha, 5), alpha = -12..12, unit==[5,20])}
}{
\epsffile[0 0 295 295]{../ps/modbess.ps}
}

\psXtc{
This is similar to the last example
except the index \texht{$\alpha$}\axiom{alpha}
takes on complex values in a \axiom{6 x 6} rectangle
centered on the origin.
}{
\graphpaste{draw((x,y) +-> real besselI(complex(x/20, y/20),5),
-60..60, -60..60, colorFunction ==
(x,y)+-> argument besselI(complex(x/20,y/20),5),
title=="besselI(x+i*y,5)", style=="shade")}

{8.3. Manipulating Symbolic Roots of a Polynomial}
\beginscroll
%
In this section we show you how to work with one root or all roots
of a polynomial.
These roots are represented symbolically (as opposed to being
numeric approximations).
See \downlink{‘‘Solution of a Single Polynomial Equation’’}
{ugxProblemOnePolPage}
in Section 8.5.2\ignore{ugxProblemOnePol} and
\downlink{‘‘Solution of Systems of Polynomial Equations’’}
{ugxProblemPolSysPage} in
Section 8.5.3\ignore{ugxProblemPolSys} for
information about solving for the roots of one or more
polynomials.

12.0.155 Using All Roots of a Polynomial

⇒ “notitle” (ugxProblemOnePolPage) 12.0.159 on page 2403

`<ug08.ht>+≡`

```
\begin{page}{ugxProblemSymRootAllPage}
{8.3.2. Using All Roots of a Polynomial}
\beginscroll
```

Use `\axiomFun{rootsOf}` to get all symbolic roots of a polynomial:

`\axiom{rootsOf(p, x)}` returns a

list of all the roots of `\axiom{p(x)}`.

If `\axiom{p(x)}` has a multiple root of order `\axiom{n}`, then that root appears `\axiom{n}` times in the list.

`\texht{\typeout{Make sure these variables are x0 etc}}{}`

```
\xctc{
```

Compute all the roots of `\axiom{x**4 + 1}`.

```
}{
```

```
\spadpaste{l := rootsOf(x**4+1,x) \bound{l}}
```

```
}
```

```
\xctc{
```

As a side effect, the variables `\axiom{\%x0}`, `\axiom{\%x1}` and `\axiom{\%x2}` are bound to the first three roots of `\axiom{x**4+1}`.

```
}{
```

```
\spadpaste{\%x0**5 \free{l}}
```

```
}
```

```
\xctc{
```

Although they all satisfy `\axiom{x**4 + 1 = 0}`, `\axiom{\%x0}`, `\axiom{\%x1}`, and `\axiom{\%x2}` are different algebraic numbers.

To find the algebraic relation that defines each of them, use `\axiomFun{definingPolynomial}`.

```
}{
```

```
\spadpaste{definingPolynomial \%x0 \free{l}}
```

```
}
```

```

```

```
}{
```

```
\spadpaste{definingPolynomial \%x1 \free{l}}
```

```
}
```

```
\xctc{
```

```
}{
```

```
\spadpaste{definingPolynomial \%x2 \free{l}}
```

```
}
```

```
\xctc{
```

We can check that the sum and product of the roots of `\axiom{x**4+1}` are

```

its trace and norm.
}{
\spadpaste{x3 := last 1 \free{1} \bound{x3}}
}
\xtc{
}{
\spadpaste{\%x0 + \%x1 + \%x2 + x3 \free{x3}}
}
\xtc{
}{
\spadpaste{\%x0 * \%x1 * \%x2 * x3 \free{x3}}
}
\xtc{
Corresponding to the pair of operations
\axiomFun{rootOf}/\axiomFun{zeroOf} in
\downlink{‘‘Solution of a Single Polynomial Equation’’}
{ugxProblemOnePolPage} in Section
8.5.2\ignore{ugxProblemOnePol}, there is an
operation \axiomFun{zerosOf} that, like \axiomFun{rootsOf}, computes
all the roots of a given polynomial, but which expresses some of them
in terms of radicals.
}{
\spadpaste{zerosOf(y**4+1,y) \bound{z}}
}
\xtc{
As you see, only one implicit algebraic number was created
(\axiom{\%y1}), and its defining equation is this.
The other three roots are expressed in radicals.

12.0.156 Computation of Eigenvalues and Eigenvectors

```

<ug08.ht>+≡
\begin{page}{ugProblemEigenPage}
{8.4. Computation of Eigenvalues and Eigenvectors}
\beginscroll
%
In this section we show you
some of Axiom's facilities for computing and
manipulating eigenvalues and eigenvectors, also called
characteristic values and characteristic vectors,
respectively.

\texht{\vskip 4pc}{ }

\xtc{
Let's first create a matrix with integer entries.
}{
\spadpaste{m1 := matrix [[1,2,1],[2,1,-2],[1,-2,4]] \bound{m1}}
}
\xtc{
To get a list of the {\it rational} eigenvalues,
use the operation \axiomFun{eigenvalues}.
}{
\spadpaste{leig := eigenvalues(m1) \free{m1} \bound{leig}}
}
\xtc{
Given an explicit eigenvalue, \axiomFun{eigenvector} computes the
eigenvectors corresponding to it.
}{
\spadpaste{eigenvector(first(leig),m1) \free{m1 leig}}
}

The operation \axiomFun{eigenvectors} returns a list of pairs of values
and vectors. When an eigenvalue is rational, Axiom gives you
the value explicitly; otherwise, its minimal polynomial is given,
(the polynomial of lowest degree with the eigenvalues as roots),
together with a parametric representation of the eigenvector using the
eigenvalue.
This means that if you ask Axiom to \axiomFun{solve}
the minimal polynomial, then you can substitute these roots
into the parametric form of the corresponding eigenvectors.

\xtc{
You must be aware that unless an exact eigenvalue has been computed,
the eigenvector may be badly in error.
}

```

```

}{
\spadpaste{eigenvectors(m1) \free{m1}}
}
\xtc{
Another possibility is to use the operation
\axiomFun{radicalEigenvectors}
tries to compute explicitly the eigenvectors
in terms of radicals.
}{
\spadpaste{radicalEigenvectors(m1) \free{m1}}
}

```

Alternatively, Axiom can compute real or complex approximations to the eigenvectors and eigenvalues using the operations `\axiomFun{realEigenvectors}` or `\axiomFun{complexEigenvectors}`. They each take an additional argument `\texht{ϵ}``{\axiom{epsilon}}` to specify the ‘precision’ required. In the real case, this means that each approximation will be within `\texht{$\pm\epsilon$}``{plus or minus \axiom{epsilon}}` of the actual result. In the complex case, this means that each approximation will be within `\texht{$\pm\epsilon$}``{plus or minus \axiom{epsilon}}` of the actual result in each of the real and imaginary parts.

```

\xtc{
The precision can be specified as a \axiomType{Float} if the results
are desired in floating-point notation, or as \axiomType{Fraction
Integer} if the results are to be expressed using rational (or complex
rational) numbers.
}{
\spadpaste{realEigenvectors(m1,1/1000) \free{m1}}
}
\xtc{
If an \axiom{n} by \axiom{n} matrix has \axiom{n} distinct eigenvalues
(and therefore \axiom{n} eigenvectors) the operation
\axiomFun{eigenMatrix} gives you a matrix of the eigenvectors.
}{
\spadpaste{eigenMatrix(m1) \free{m1}}
}
\xtc{
}{
\spadpaste{m2 := matrix [[-5,-2],[18,7]] \bound{m2}}
}
\xtc{
}{
\spadpaste{eigenMatrix(m2) \free{m2}}
}

```

```

%
%
\xtc{
  If a symmetric matrix
  has a basis of orthonormal eigenvectors, then
  \axiomFun{orthonormalBasis} computes a list of these vectors.
}{
  \spadpaste{m3 := matrix [[1,2],[2,1]] \bound{m3}}
}
\xtc{
}{
  \spadpaste{orthonormalBasis(m3) \free{m3}}
}

%
In this section we discuss the Axiom facilities for solving
systems of linear equations, finding the roots of polynomials and
solving systems of polynomial equations.
For a discussion of the solution of differential equations, see
\downlink{‘‘Solution of Differential Equations’’}{ugProblemDEQPage} in
Section 8.10\ignore{ugProblemDEQ}.

12.0.158 Solution of Systems of Linear Equations

<ug08.ht>+≡

```
\begin{page}{\ugxProblemLinSysPage}
{8.5.1. Solution of Systems of Linear Equations}
\beginscroll
```

You can use the operation `\axiomFun{solve}` to solve systems of linear equations.

The operation `\axiomFun{solve}` takes two arguments, the list of equations and the list of the unknowns to be solved for. A system of linear equations need not have a unique solution.

```
\xctc{
To solve the linear system:
\centerline{{\axiom{ x + y + z = 8} }}
\centerline{{\axiom{3*x - 2*y + z = 0} }}
\centerline{{\axiom{ x + 2*y + 2*z = 17}}}}
evaluate this expression.
}{
\spadpaste{solve([x+y+z=8,3*x-2*y+z=0,x+2*y+2*z=17],[x,y,z])}
}
```

Parameters are given as new variables starting with a percent sign and `\spadSyntax{\%}` and the variables are expressed in terms of the parameters. If the system has no solutions then the empty list is returned.

```
\xctc{
When you solve the linear system
\centerline{{\axiom{ x + 2*y + 3*z = 2} }}
\centerline{{\axiom{2*x + 3*y + 4*z = 2} }}
\centerline{{\axiom{3*x + 4*y + 5*z = 2}}}}
with this expression
you get a solution involving a parameter.
){
\spadpaste{solve([x+2*y+3*z=2,2*x+3*y+4*z=2,3*x+4*y+5*z=2],[x,y,z])}
}
```

The system can also be presented as a matrix and a vector. The matrix contains the coefficients of the linear equations and the vector contains the numbers appearing on the right-hand sides of the equations. You may input the matrix as a list of rows and the vector as a list of its elements.

```

\xtc{
To solve the system:
\centerline{{\axiom{ x + y + z = 8} }}
\centerline{{\axiom{3*x - 2*y + z = 0} }}
\centerline{{\axiom{ x + 2*y + 2*z = 17}}}
in matrix form you would evaluate this expression.
}{
\spadpaste{solve([[1,1,1],[3,-2,1],[1,2,2]],[8,0,17]])}
}

```

The solutions are presented as a `\pspadtype{Record}` with two components: the component `\texht{{\it particular}}{\tt particular}` contains a particular solution of the given system or the item `{\tt "failed"}` if there are no solutions, the component `\texht{{\it basis}}{\tt basis}` contains a list of vectors that are a basis for the space of solutions of the corresponding homogeneous system.

If the system of linear equations does not have a unique solution, then the `\texht{{\it basis}}{\tt basis}` component contains non-trivial vectors.

```

\xtc{
This happens when you solve the linear system
\centerline{{\axiom{ x + 2*y + 3*z = 2} }}
\centerline{{\axiom{2*x + 3*y + 4*z = 2} }}
\centerline{{\axiom{3*x + 4*y + 5*z = 2}}}
with this command.
}{
\spadpaste{solve([[1,2,3],[2,3,4],[3,4,5]],[2,2,2]])}
}

```

All solutions of this system are obtained by adding the particular solution with a linear combination of the `\texht{{\it basis}}{\tt basis}` vectors.

When no solution exists then `{\tt "failed"}` is returned as the `\texht{{\it particular}}{\tt particular}` component, as follows:

```

\xtc{
}{
\spadpaste{solve([[1,2,3],[2,3,4],[3,4,5]],[2,3,2]])}
}

```

When you want to solve a system of homogeneous equations (that is, a system where the numbers on the right-hand sides of the

equations are all zero) in the matrix form you can omit the second argument and use the `\axiomFun{nullSpace}` operation.

```

\xtc{
This computes the solutions of the following system of equations:
\centerline{{\axiom{ x + 2*y + 3*z = 0} }}
\centerline{{\axiom{2*x + 3*y + 4*z = 0} }}
\centerline{{\axiom{3*x + 4*y + 5*z = 0}}}
The result is given as a list of vectors and
these vectors form a basis for the solution space.
}{
\spadpaste{nullSpace([[1,2,3],[2,3,4],[3,4,5]])}
}

12.0.159 Solution of a Single Polynomial Equation

(ug08.ht)+≡

```
\begin{page}{ugxProblemOnePolPage}
{8.5.2. Solution of a Single Polynomial Equation}
\beginscroll
```

Axiom can solve polynomial equations producing either approximate or exact solutions. Exact solutions are either members of the ground field or can be presented symbolically as roots of irreducible polynomials.

```
\xctc{
This returns the one rational root along with an irreducible
polynomial describing the other solutions.
}{
\spadpaste{solve(x**3 = 8,x)}
}
\xctc{
If you want solutions expressed in terms of radicals you would use this
instead.
}{
\spadpaste{radicalSolve(x**3 = 8,x)}
}
```

The `\axiomFun{solve}` command always returns a value but `\axiomFun{radicalSolve}` returns only the solutions that it is able to express in terms of radicals.

If the polynomial equation has rational coefficients you can ask for approximations to its real roots by calling `solve` with a second argument that specifies the ‘‘precision’’ `\texht{ϵ}``\axiom{epsilon}`. This means that each approximation will be within `\texht{$\pm\epsilon$}` plus or minus `\axiom{epsilon}` of the actual result.

```
\xctc{
Notice that the type of second argument controls the type of the result.
}{
\spadpaste{solve(x**4 - 10*x**3 + 35*x**2 - 50*x + 25,.0001)}
}
\xctc{
If you give a floating-point precision you get a floating-point result;
if you give the precision as a rational number you get a rational result.
}{
```

```

\spadpaste{solve(x**3-2,1/1000)}
}
\xtc{
If you want approximate complex results you should use the
command \axiomFun{complexSolve} that takes the same precision argument
\texht{${\epsilon}}{\axiom{epsilon}}.
}{
\spadpaste{complexSolve(x**3-2,.0001)}
}
\xtc{
Each approximation will be within
\texht{${\pm\epsilon}}{plus or minus \axiom{epsilon}} of the actual result
in each of the real and imaginary parts.
}{
\spadpaste{complexSolve(x**2-2*\%i+1,1/100)}
}

```

Note that if you omit the `\axiomOp{=}` from the first argument Axiom generates an equation by equating the first argument to zero. Also, when only one variable is present in the equation, you do not need to specify the variable to be solved for, that is, you can omit the second argument.

```

\xtc{
Axiom can also solve equations involving rational functions.
Solutions where the denominator vanishes are discarded.
}{
\spadpaste{radicalSolve(1/x**3 + 1/x**2 + 1/x = 0,x)}
}

12.0.160 Solution of Systems of Polynomial Equations

⇒ “notitle” (ugxProblemOnePolPage) 12.0.159 on page 2403

`<ug08.ht>+≡`

```
\begin{page}{ugxProblemPolSysPage}
{8.5.3. Solution of Systems of Polynomial Equations}
\beginscroll
```

Given a system of equations of rational functions with exact coefficients:

```
\centerline{{\axiom{p1(x1,...,xn)} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{pm(x1,...,xn)}}}
```

Axiom can find

numeric or symbolic solutions.

The system is first split into irreducible components, then for each component, a triangular system of equations is found that reduces the problem to sequential solution of univariate polynomials resulting from substitution of partial solutions from the previous stage.

```
\centerline{{\axiom{q1(x1,...,xn)} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{.} }}
\centerline{{\axiom{qm(xn)}}}
```

Symbolic solutions can be presented using ‘‘implicit’’ algebraic numbers defined as roots of irreducible polynomials or in terms of radicals.

Axiom can also find approximations to the real or complex roots of a system of polynomial equations to any user-specified accuracy.

The operation `\axiomFun{solve}` for systems is used in a way similar to `\axiomFun{solve}` for single equations.

Instead of a polynomial equation, one has to give a list of equations and instead of a single variable to solve for, a list of variables.

For solutions of single equations see

```
\downlink{‘‘Solution of a Single Polynomial Equation’’}
{ugxProblemOnePolPage} in Section 8.5.2\ignore{ugxProblemOnePol}.
```

%

```
\xctc{
```

Use the operation `\axiomFun{solve}` if you want implicitly presented solutions.

```

}{
\spadpaste{solve([3*x**3 + y + 1,y**2 -4],[x,y])}
}
\xtc{
}{
\spadpaste{solve([x = y**2-19,y = z**2+x+3,z = 3*x],[x,y,z])}
}
\xtc{
Use \axiomFun{radicalSolve} if you want your solutions expressed
in terms of radicals.
}{
\spadpaste{radicalSolve([3*x**3 + y + 1,y**2 -4],[x,y])}
}

```

To get numeric solutions you only need to give the list of equations and the precision desired.
The list of variables would be redundant information since there can be no parameters for the numerical solver.

```

\xtc{
If the precision is expressed as a floating-point number you get
results expressed as floats.
}{
\spadpaste{solve([x**2*y - 1,x*y**2 - 2],.01)}
}
\xtc{
To get complex numeric solutions, use the operation \axiomFun{complexSolve},
which takes the same arguments as in the real case.
}{
\spadpaste{complexSolve([x**2*y - 1,x*y**2 - 2],1/1000)}
}
\xtc{
It is also possible to solve systems of equations in rational functions
over the rational numbers.
Note that \axiom{[x = 0.0, a = 0.0]} is not returned as a solution since
the denominator vanishes there.
}{
\spadpaste{solve([x**2/a = a,a = a*x],.001)}
}
\xtc{
When solving equations with
denominators, all solutions where the denominator vanishes are
discarded.
}{
\spadpaste{radicalSolve([x**2/a + a + y**3 - 1,a*y + a + 1],[x,y])}
}

```

```

12.0.161 Limits

```

<ug08.ht>+≡
\begin{page}{ugProblemLimitsPage}{8.6. Limits}
\beginscroll
%
To compute a limit, you must specify a functional expression,
a variable, and a limiting value for that variable.
If you do not specify a direction, Axiom attempts to
compute a two-sided limit.

\xtc{
Issue this to compute the limit
\texht{ $\lim_{x \rightarrow 1} \frac{x^2 - 3x + 2}{x^2 - 1}$ }
of  $\text{\axiom{(x**2 - 3*x + 2)/(x**2 - 1)}}$  as  $\text{\axiom{x}}$  approaches  $\text{\axiom{1}}$ .}
}{
\spadpaste{limit((x**2 - 3*x + 2)/(x**2 - 1),x = 1)}
}

```

Sometimes the limit when approached from the left is different from the limit from the right and, in this case, you may wish to ask for a one-sided limit. Also, if you have a function that is only defined on one side of a particular value, you can compute a one-sided limit.

```

\xtc{
The function  $\text{\axiom{log(x)}}$  is only defined to the right of zero,
that is, for  $\text{\axiom{x} > 0}$ .
Thus, when computing limits of functions involving  $\text{\axiom{log(x)}}$ ,
you probably want a ‘‘right-hand’’ limit.
}{
\spadpaste{limit(x * log(x),x = 0,"right")}
}
\xtc{
When you do not specify  $\text{\axiom{"right"}}$  or  $\text{\axiom{"left"}}$  as the
optional fourth argument,  $\text{\axiomFun{limit}}$  tries to compute a
two-sided limit.
Here the limit from the left does not exist, as Axiom
indicates when you try to take a two-sided limit.
}{
\spadpaste{limit(x * log(x),x = 0)}
}

```

A function can be defined on both sides of a particular value, but tend to different limits as its variable approaches that value from the left and from the right.

We can construct an example of this as follows:

Since

$\sqrt{y^2}$ is simply the absolute value of $\sqrt{y^2}$,

the function

$\sqrt{y^2} / y$ is simply the sign (± 1) of the nonzero

real number y .
Therefore,

$\sqrt{y^2} / y = -1$ for $y < 0$ and

$\sqrt{y^2} / y = +1$ for $y > 0$.

{

This is what happens when we take the limit at $y = 0$.

The answer returned by Axiom gives both a

‘‘left-hand’’ and a ‘‘right-hand’’ limit.

}

`\spadpaste{limit(sqrt(y**2)/y,y = 0)}`

}

{

Here is another example, this time using a more complicated function.

}

`\spadpaste{limit(sqrt(1 - cos(t))/t,t = 0)}`

}

You can compute limits at infinity by passing either

$+\infty$ or $-\infty$ as the third argument of `\axiomFun{limit}`.

{

To do this, use the constants

`\axiom{+%plusInfinity}` and `\axiom{-%minusInfinity}`.

}

`\spadpaste{limit(sqrt(3*x**2 + 1)/(5*x),x = +%plusInfinity)}`

}

{

}

`\spadpaste{limit(sqrt(3*x**2 + 1)/(5*x),x = %minusInfinity)}`

}

{

You can take limits of functions with parameters.

As you can see, the limit is expressed in terms of the parameters.

}

`\spadpaste{limit(sinh(a*x)/tan(b*x),x = 0)}`

}

When you use `\axiomFun{limit}`, you are taking the limit of a real function of a real variable.

```
\xctc{
```

When you compute this, Axiom returns `\axiom{0}` because, as a function of a real variable, `\axiom{sin(1/z)}` is always between `\axiom{-1}` and `\axiom{1}`, so `\axiom{z * sin(1/z)}` tends to `\axiom{0}` as `\axiom{z}` tends to `\axiom{0}`.

```
}{
```

```
\spadpaste{limit(z * sin(1/z), z = 0)}
```

```
}
```

However, as a function of a `{\it complex}` variable, `\axiom{sin(1/z)}` is badly behaved near `\axiom{0}` (one says that `\axiom{sin(1/z)}` has an `{\it essential singularity}` at `\axiom{z = 0}`).

```
\xctc{
```

When viewed as a function of a complex variable, `\axiom{z * sin(1/z)}` does not approach any limit as `\axiom{z}` tends to `\axiom{0}` in the complex plane. Axiom indicates this when we call `\axiomFun{complexLimit}`.

```
}{
```

```
\spadpaste{complexLimit(z * sin(1/z), z = 0)}
```

```
}
```

You can also take complex limits at infinity, that is, limits of a function of `\axiom{z}` as `\axiom{z}` approaches infinity on the Riemann sphere. Use the symbol `\axiom{\%infinity}` to denote ‘‘complex infinity.’’

```
\xctc{
```

As above, to compute complex limits rather than real limits, use `\axiomFun{complexLimit}`.

```
}{
```

```
\spadpaste{complexLimit((2 + z)/(1 - z), z = \%infinity)}
```

```
}
```

```
\xctc{
```

In many cases, a limit of a real function of a real variable exists when the corresponding complex limit does not.

This limit exists.

```
}{
```

```
\spadpaste{limit(sin(x)/x, x = \%plusInfinity)}
```

```
}
```

```
\xctc{
```

But this limit does not.

```
}{
```

```
\spadpaste{complexLimit(sin(x)/x, x = \%infinity)}
```

```
}
```

```

12.0.163 Integration

⇒ “notitle” (ugxProblemSymRootAllPage) 12.0.155 on page 2382

```

<ug08.ht>+≡
\begin{page}{ugProblemIntegrationPage}{8.8. Integration}
\beginscroll
%
Integration is the reverse process of differentiation, that is,
an {\it integral} of a function \axiom{f} with respect to a variable
\axiom{x} is any function \axiom{g} such that \axiom{D(g,x)}
is equal to \axiom{f}.
\xtc{
The package \axiomType{FunctionSpaceIntegration} provides the top-level
integration operation, \axiomFunFrom{integrate}{FunctionSpaceIntegration},
for integrating real-valued elementary functions.
}{
\spadpaste{integrate(cosh(a*x)*sinh(a*x), x)}
}
\xtc{
Unfortunately, antiderivatives of most functions cannot be expressed in
terms of elementary functions.
}{
\spadpaste{integrate(log(1 + sqrt(a * x + b)) / x, x)}
}
Given an elementary function to integrate, Axiom returns a formal
integral as above only when it can prove that the integral is not
elementary and not when it cannot determine the integral.
In this rare case it prints a message that it cannot
determine if an elementary integral exists.
%
\xtc{
Similar functions may have antiderivatives
that look quite different because the form of the antiderivative
depends on the sign of a constant that appears in the function.
}{
\spadpaste{integrate(1/(x**2 - 2),x)}
}
\xtc{
}{
\spadpaste{integrate(1/(x**2 + 2),x)}
}
%
If the integrand contains parameters, then there may be several possible
antiderivatives, depending on the signs of expressions of the parameters.

```

```
\xctc{
In this case Axiom returns a list of answers that cover all
the possible cases.
Here you
use the answer involving the square root of \axiom{a} when \axiom{a > 0} and
the answer involving the square root of \axiom{-a} when \axiom{a < 0}.
}{
\spadpaste{integrate(x**2 / (x**4 - a**2), x)}
}
```

If the parameters and the variables of integration can be complex numbers rather than real, then the notion of sign is not defined. In this case all the possible answers can be expressed as one complex function.

To get that function, rather than a list of real functions, use `\axiomFunFrom{complexIntegrate}{FunctionSpaceComplexIntegration}`, which is provided by the package `\axiomType{FunctionSpaceComplexIntegration}`.

```
\xctc{
This operation is used for
integrating complex-valued elementary functions.
}{
\spadpaste{complexIntegrate(x**2 / (x**4 - a**2), x)}
}
\xctc{
As with the real case,
antiderivatives for most complex-valued functions cannot be expressed
in terms of elementary functions.
}{
\spadpaste{complexIntegrate(log(1 + sqrt(a * x + b)) / x, x)}
}
```

Sometimes `\axiomFun{integrate}` can involve symbolic algebraic numbers such as those returned by `\axiomFunFrom{rootOf}{Expression}`. To see how to work with these strange generated symbols (such as `\axiom{\%\%a0}`), see `\downlink{'Using All Roots of a Polynomial'}{ugxProblemSymRootAllPage}` in Section 8.3.2\ignore{ugxProblemSymRootAll}.

Definite integration is the process of computing the area between the `\axiom{x}`-axis and the curve of a function `\axiom{f(x)}`. The fundamental theorem of calculus states that if `\axiom{f}` is continuous on an interval `\axiom{a..b}` and if there exists a function `\axiom{g}` that is differentiable on `\axiom{a..b}` and such that `\axiom{D(g, x)}` is equal to `\axiom{f}`, then the definite integral of `\axiom{f}` for

`\axiom{x}` in the interval `\axiom{a..b}` is equal to `\axiom{g(b) - g(a)}`.

```
\xctc{
The package \axiomType{RationalFunctionDefiniteIntegration} provides
the top-level definite integration operation,
\axiomFunFrom{integrate}{RationalFunctionDefiniteIntegration},
for integrating real-valued rational functions.
}{
\spadpaste{integrate((x**4 - 3*x**2 + 6)/(x**6-5*x**4+5*x**2+4), x = 1..2)}
}
```

Axiom checks beforehand that the function you are integrating is defined on the interval `\axiom{a..b}`, and prints an error message if it finds that this is not case, as in the following example:

```
\begin{verbatim}
integrate(1/(x**2-2), x = 1..2)

>> Error detected within library code:
    Pole in path of integration
    You are being returned to the top level
    of the interpreter.
```

```
\end{verbatim}
```

When parameters are present in the function, the function may or may not be defined on the interval of integration.

```
\xctc{
If this is the case, Axiom issues a warning that a pole might
lie in the path of integration, and does not compute the integral.
}{
\spadpaste{integrate(1/(x**2-a), x = 1..2)}
}
```

If you know that you are using values of the parameter for which the function has no pole in the interval of integration, use the string `{\tt "noPole"}` as a third argument to

```
\axiomFunFrom{integrate}{RationalFunctionDefiniteIntegration}:
```

```
%
\xctc{
The value here is, of course, incorrect if \axiom{sqrt(a)} is between
\axiom{1} and \axiom{2.}
}{
\spadpaste{integrate(1/(x**2-a), x = 1..2, "noPole")}
}
```

```
\endscroll
```

```

```

```
%
```

Axiom has very sophisticated facilities for working with power series.

Infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing the additional coefficients if needed.

```
%
```

The system command that determines how many terms of a series is displayed is `\spadcmd{set streams calculate}`.

For the purposes of this book, we have used this system command to display fewer than ten terms.

Series can be created from expressions, from functions for the series coefficients, and from applications of operations on existing series.

The most general function for creating a series is called `\axiomFun{series}`, although you can also use `\axiomFun{taylor}`, `\axiomFun{laurent}` and `\axiomFun{puiseux}` in situations where you know what kind of exponents are involved.

For information about solving differential equations in terms of power series, see

```

This is the easiest way to create a power series.

This tells Axiom that `\axiom{x}` is to be treated as a power series, so functions of `\axiom{x}` are again power series.

```
}{
```

```
\spadpaste{x := series 'x \bound{x}}
```

```
}
```

```
%
```

We didn't say anything about the coefficients of the power series, so the coefficients are general expressions over the integers. This allows us to introduce denominators, symbolic constants, and other variables as needed.

```
\xctc{
```

Here the coefficients are integers (note that the coefficients are the Fibonacci numbers).

```
}{
```

```
\spadpaste{1/(1 - x - x**2) \free{x}}
```

```
}
```

```
\xctc{
```

This series has coefficients that are rational numbers.

```
}{
```

```
\spadpaste{sin(x) \free{x}}
```

```
}
```

```
\xctc{
```

When you enter this expression

you introduce the symbolic constants `\axiom{sin(1)}` and `\axiom{cos(1)}`.

```
}{
```

```
\spadpaste{sin(1 + x) \free{x}}
```

```
}
```

```
\xctc{
```

When you enter the expression

the variable `\axiom{a}` appears in the resulting series expansion.

```

}{
\spadpaste{sin(a * x) \free{x}}
}

```

```

\xtc{
You can also convert an expression into a series expansion.
This expression creates the series expansion of \axiom{1/log(y)}
about \axiom{y = 1}.
For details and more examples, see
\downlink{‘‘Converting to Power Series’’}
{ugxProblemSeriesConversionsPage} in Section
8.9.5\ignore{ugxProblemSeriesConversions}.
}{
\spadpaste{series(1/log(y),y = 1)}
}

```

You can create power series with more general coefficients.
 You normally accomplish this via a type declaration (see
[\downlink{‘‘Declarations’’}{ugTypesDeclarePage}](#) in Section
 2.3\ignore{ugTypesDeclare}).

See
[\downlink{‘‘Functions on Power Series’’}](#)
[{ugxProblemSeriesFunctionsPage}](#)
 in Section 8.9.4\ignore{ugxProblemSeriesFunctions}
 for some warnings about working with declared series.

```

\xtc{
We declare that \axiom{y} is a one-variable Taylor series
(\axiomType{UTS} is the abbreviation for
\axiomType{UnivariateTaylorSeries})
in the variable \axiom{z} with \axiomType{FLOAT}
(that is, floating-point) coefficients, centered about \axiom{0.}
Then, by assignment, we obtain the Taylor expansion of
\axiom{exp(z)} with floating-point coefficients.
}{
\spadpaste{y : UTS(FLOAT,'z,0) := exp(z) \bound{y}}
}

```

You can also create a power series by giving an explicit formula
 for its $\text{\eth{\axiom{n}}}$ coefficient.
 For details and more examples, see
[\downlink{‘‘Power Series from Formulas’’}{ugxProblemSeriesFormulaPage}](#)
 in Section 8.9.6\ignore{ugxProblemSeriesFormula}.

```

\xtc{
To create a series about

```

\axiom{w = 0} whose \eth{\axiom{n}} Taylor coefficient
is \axiom{1/n!}, you can evaluate this expression.
This is the Taylor expansion of \axiom{exp(w)} at \axiom{w = 0}.

```
{
\spadpaste{series(1/factorial(n),n,w = 0)}
}
%
```

12.0.166 Coefficients of Power Series

<ug08.ht>+≡

```
\begin{page}{ugxProblemSeriesCoefficientsPage}
{8.9.2. Coefficients of Power Series}
\beginscroll
```

You can extract any coefficient from a power series---even one that hasn't been computed yet.

This is possible because in Axiom, infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing the additional coefficients.

(This is known as *{\it lazy evaluation}*.) When you ask for a coefficient that hasn't yet been computed, Axiom computes whatever additional coefficients it needs and then stores them in the representation of the power series.

```
\xctc{
Here's an example of how to extract the coefficients of a power series.
}{
\spadpaste{x := series(x) \bound{x}}
}
\xctc{
}{
\spadpaste{y := exp(x) * sin(x) \free{x} \bound{y}}
}
\xctc{
This coefficient is readily available.
}{
\spadpaste{coefficient(y,6) \free{y}}
}
\xctc{
But let's get the fifteenth coefficient of \axiom{y}.
}{
\spadpaste{coefficient(y,15) \free{y} \bound{y15}}
}
\xctc{
If you look at \axiom{y}
then you see that the coefficients up to order \axiom{15}
have all been computed.
}{
\spadpaste{y \free{y15}}
}

12.0.168 Functions on Power Series

<ug08.ht>+≡

```
\begin{page}{ugxProblemSeriesFunctionsPage}
{8.9.4. Functions on Power Series}
\beginscroll
```

Once you have created a power series, you can apply transcendental functions

(for example, `\axiomFun{exp}`, `\axiomFun{log}`, `\axiomFun{sin}`, `\axiomFun{tan}`, `\axiomFun{cosh}`, etc.) to it.

```
\labelSpace{1pc}
%
\xtc{
To demonstrate this, we first create the power series
expansion of the rational function
\texht{

$$\frac{x^2}{1 - 6x + x^2}$$

}{
\axiom{x**2/(1 - 6*x + x**2)}
}
about \axiom{x = 0}.
}{
\spadpaste{x := series 'x \bound{x}}
}
%
\xtc{
}{
\spadpaste{rat := x**2 / (1 - 6*x + x**2) \free{x} \bound{rat}}
}
%
%
\xtc{
If you want to compute the series expansion of
\texht{

$$\sin\left(\frac{x^2}{1 - 6x + x^2}\right)$$

}{
\axiom{sin(x**2/(1 - 6*x + x**2))}
}
you simply compute the sine of \axiom{rat}.
}{
\spadpaste{sin(rat) \free{rat}}
}
%
%
```

```

\beginImportant
\noindent {\bf Warning:}
the type of the coefficients of a power series may
affect the kind of computations that you can do with that series.
This can only happen when you have made a declaration to
specify a series domain with a certain type of coefficient.
\endImportant

\xtc{
If you evaluate
then you have declared that \axiom{y} is a one variable Taylor series
(\axiomType{UTS} is the abbreviation for \axiomType{UnivariateTaylorSeries})
in the variable \axiom{y} with \axiomType{FRAC INT}
(that is, fractions of integer) coefficients, centered about \axiom{0}.
}{
\spadpaste{y : UTS(FRAC INT,y,0) := y \bound{y}}
}
%
\xtc{
You can now compute certain power series in \axiom{y},
{\it provided} that these series have rational coefficients.
}{
\spadpaste{exp(y) \free{y}}
}
%
\xtc{
You can get examples of such series
by applying transcendental functions to
series in \axiom{y} that have no constant terms.
}{
\spadpaste{tan(y**2) \free{y}}
}
%
\xtc{
}{
\spadpaste{cos(y + y**5) \free{y}}
}
%
%
\xtc{
Similarly, you can compute the logarithm of a power series with rational
coefficients if the constant coefficient is \axiom{1.}
}{
\spadpaste{log(1 + sin(y)) \free{y}}
}
}

```

%
 If you wanted to apply, say, the operation `\axiomFun{exp}` to a power series with a nonzero constant coefficient `\texht{a_0}``\axiom{a0}`, then the constant coefficient of the result would be `\texht{e^{a_0}}``\axiom{exp(a0)}`, which is `\it not` a rational number. Therefore, evaluating `\axiom{exp(2 + tan(y))}` would generate an error message.

If you want to compute the Taylor expansion of `\axiom{exp(2 + tan(y))}`, you must ensure that the coefficient domain has an operation `\axiomFun{exp}` defined for it. An example of such a domain is `\axiomType{Expression Integer}`, the type of formal functional expressions over the integers.

```
\xctc{
When working with coefficients of this type,
}{
\spadpaste{z : UTS(EXPR INT,z,0) := z \bound{z}}
}
```

```
\xctc{
this presents no problems.
}{
\spadpaste{exp(2 + tan(z)) \free{z}}
}
```

%
 Another way to create Taylor series whose coefficients are expressions over the integers is to use `\axiomFun{taylor}` which works similarly to `\axiomFun{series}`.

```
%
\xctc{
This is equivalent to the previous computation, except that now we
are using the variable \axiom{w} instead of \axiom{z}.
}{
\spadpaste{w := taylor 'w \bound{w}}
}
\xctc{
}{
\spadpaste{exp(2 + tan(w)) \free{w}}
}
```

```
\endscroll

12.0.169 Converting to Power Series

<ug08.ht>+≡

```
\begin{page}{ugxProblemSeriesConversionsPage}
{8.9.5. Converting to Power Series}
\beginscroll
```

The `\axiomType{ExpressionToUnivariatePowerSeries}` package provides operations for computing series expansions of functions.

```
\labelSpace{1pc}
\xtc{
Evaluate this
to compute the Taylor expansion of \axiom{sin x} about
\axiom{x = 0}.
The first argument, \axiom{sin(x)}, specifies the function whose series
expansion is to be computed and the second argument, \axiom{x = 0},
specifies that the series is to be expanded in power of \axiom{(x - 0)},
that is, in power of \axiom{x}.
}{
\spadpaste{taylor(sin(x),x = 0)}
}
\xtc{
Here is the Taylor expansion of \axiom{sin x} about
\texht{$x = \frac{\pi}{6}$}\axiom{x = \%pi/6}:
}{
\spadpaste{taylor(sin(x),x = \%pi/6)}
}
```

The function to be expanded into a series may have variables other than the series variable.

```
%
\xtc{
For example, we may expand \axiom{tan(x*y)} as a Taylor series in
\axiom{x}
}{
\spadpaste{taylor(tan(x*y),x = 0)}
}
%
\xtc{
or as a Taylor series in \axiom{y}.
}{
\spadpaste{taylor(tan(x*y),y = 0)}
}
\xtc{
A more interesting function is
```

```

\texht{\displaystyle t e^{\displaystyle t} } \over
{\displaystyle e^t - 1}{(t * \%e**(x*t))/(\%e**t - 1)}.
When we expand this function as a Taylor series in \axiom{t}
the \eth{\axiom{n}} order coefficient is the \eth{\axiom{n}} Bernoulli
polynomial
divided by \axiom{n!}.
}{
\spadpaste{bern := taylor(t*exp(x*t)/(exp(t) - 1),t = 0) \bound{bern}}
}
\xtc{
Therefore, this and the next expression
produce the same result.
}{
\spadpaste{factorial(6) * coefficient(bern,6) \free{bern}}
}
\xtc{
}{
\spadpaste{bernoulliB(6,x)}
}

```

Technically, a series with terms of negative degree is not considered to be a Taylor series, but, rather, a

{\it Laurent series}.

If you try to compute a Taylor series expansion of

$\frac{x}{\log x}$ at $x = 1$ via `\axiom{taylor(x/log(x),x = 1)}`

you get an error message.

The reason is that the function has a {\it pole} at $x = 1$, meaning that

its series expansion about this point has terms of negative degree.

A series with finitely many terms of negative degree is called a Laurent series.

\xtc{

You get the desired series expansion by issuing this.

{

\spadpaste{laurent(x/log(x),x = 1)}

}

Similarly, a series with terms of fractional degree is neither a Taylor series nor a Laurent series. Such a series is called a {\it Puiseux series}. The expression `\axiom{laurent(sqrt(sec(x)),x = 3 * \%pi/2)}` results in an error message because the series expansion about this point has terms of fractional degree.

\xtc{

However, this command produces what you want.

```

}{
\spadpaste{puiseux(sqrt(sec(x)),x = 3 * \%pi/2)}
}

```

Finally, consider the case of functions that do not have Puiseux expansions about certain points. An example of this is $\text{\texht{\$x^x\$}}{\backslash\text{axiom}\{x^x\}}$ about $\text{\axiom}\{x = 0\}$. $\text{\axiom}\{\text{puiseux}(x**x,x=0)\}$ produces an error message because of the type of singularity of the function at $\text{\axiom}\{x = 0\}$.

```

\xtc{
The general function \axiomFun{series} can be used in this case.
Notice that the series returned is not, strictly speaking, a power series
because of the \axiom{log(x)} in the expansion.
}{
\spadpaste{series(x**x,x=0)}
}

```

```

\beginImportant
The operation \axiomFun{series} returns the most general type of
infinite series.
The user who is not interested in distinguishing
between various types of infinite series may wish to use this operation
exclusively.
\endImportant

```

```

```
<ug08.ht>+≡
\begin{page}{ugxProblemSeriesFormulaPage}
{8.9.6. Power Series from Formulas}
\beginscroll
```

The `\axiomType{GenerateUnivariatePowerSeries}` package enables you to create power series from explicit formulas for their `\eth{\axiom{n}}` coefficients. In what follows, we construct series expansions for certain transcendental functions by giving formulas for their coefficients. You can also compute such series expansions directly simply by specifying the function and the point about which the series is to be expanded. See

`\downlink{‘‘Converting to Power Series’’}`
`{ugxProblemSeriesConversionsPage}` in Section
 8.9.5`\ignore{ugxProblemSeriesConversions}`
 for more information.

Consider the Taylor expansion of `\texht{e^x}``{\axiom{\%e**x}}`
 about `\axiom{x = 0}`:

```
\texht{\narrowDisplay{%
\begin{array}{ccl}
e^x &=& \displaystyle 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \cdots \ \ \ \
&=& \displaystyle \sum_{n=0}^{\infty} \frac{x^n}{n!}
\end{array}}}%
}{
\begin{verbatim}
%e**x = 1 + x + x**2/2 + x**3/6 + ...
      = sum from n=0 to n=%infty of x**n / n!
\end{verbatim}
}
```

The `\eth{\axiom{n}}` Taylor coefficient is `\axiom{1/n!}`.

```
%
\xtc{
This is how you create this series in Axiom.
}{
\spadpaste{series(n +-> 1/factorial(n),x = 0)}
}
```

The first argument specifies a formula for the `\eth{\axiom{n}}`

coefficient by giving a function that maps $\text{\axiom{n}}$ to $\text{\axiom{1/n!}}$. The second argument specifies that the series is to be expanded in powers of $\text{\axiom{(x - 0)}}$, that is, in powers of $\text{\axiom{x}}$. Since we did not specify an initial degree, the first term in the series was the term of degree 0 (the constant term). Note that the formula was given as an anonymous function. These are discussed in [\downlink{'Anonymous Functions'}{\ugUserAnonPage}](#) in Section 6.17\ignore{\ugUserAnon}.

Consider the Taylor expansion of $\text{\axiom{log x}}$ about $\text{\axiom{x = 1}}$:

```
\texht{\narrowDisplay{%
\begin{array}{ccl}
\log(x) &=& \displaystyle (x - 1) - \frac{(x - 1)^2}{2} +
\frac{(x - 1)^3}{3} - \cdots \\\
&=& \displaystyle \sum_{n = 1}^{\infty} (-1)^{n-1} \frac{(x - 1)^n}{n}
\end{array}}%
}{
\begin{verbatim}
log x = (x - 1) - \frac{(x - 1)^2}{2} + \frac{(x - 1)^3}{3} - ...
      = sum from n=1 to n=infty of (-1)**(n-1) (x - 1)**n / n
\end{verbatim}
}
```

If you were to evaluate the expression

```
\axiom{series(n +-> (-1)**(n-1) / n, x = 1)}
```

you would get an error message because Axiom would try to calculate a term of degree $\text{\axiom{0}}$ and therefore divide by $\text{\axiom{0.}}$

```
\xctc{
Instead, evaluate this.
The third argument, \axiom{1..}, indicates that only terms of degree
\axiom{n = 1, ...} are to be computed.
}{
\spadpaste{series(n +-> (-1)**(n-1)/n, x = 1, 1..)}
}
%
```

Next consider the Taylor expansion of an odd function, say,

```
\axiom{sin(x)}:
\begin{verbatim}
sin x = x - x**3/3! + x**5/5! - ...
\end{verbatim}
```

Here every other coefficient is zero and we would like to give an explicit formula only for the odd Taylor coefficients.

```
%
\xctc{
```

This is one way to do it. The third argument, $\text{\axiom{1..}}$, specifies

that the first term to be computed is the term of degree 1. The fourth argument, `\axiom{2}`, specifies that we increment by `\axiom{2}` to find the degrees of subsequent terms, that is, the next term is of degree `\axiom{1 + 2}`, the next of degree `\axiom{1 + 2 + 2}`, etc.

```
{
\spadpaste{series(n +-> (-1)**((n-1)/2)/factorial(n),x = 0,1..,2)}
}
%
```

```
\xctc{
```

The initial degree and the increment do not have to be integers.

For example, this expression produces a series expansion of

```
\texht{$\sin(x^{\frac{1}{3}})$}\axiom{sin(x**(1/3))}.
```

```
{
\spadpaste{series(n +-> (-1)**((3*n-1)/2)/factorial(3*n),x = 0,1/3..,2/3)}
}
```

```
\xctc{
```

While the increment must be positive, the initial degree may be negative.

This yields the Laurent expansion of `\axiom{csc(x)}` at

```
\axiom{x = 0}.
```

```
%
```

```
{
```

```
\spadpaste{cscx :=
series(n +-> (-1)**((n-1)/2) * 2 * (2**n-1) * bernoulli(numer(n+1))
/ factorial(n+1), x=0, -1..,2) \bound{cscx}}
}
```

```
\xctc{
```

Of course, the reciprocal of this power series is the Taylor expansion of `\axiom{sin(x)}`.

```
{
```

```
\spadpaste{1/cscx \free{cscx}}
```

```
}
```

```
%
```

```
\xctc{
```

As a final example,

here is the Taylor expansion of `\axiom{asin(x)}` about `\axiom{x = 0}`.

```
{
```

```
\spadpaste{asinx := series(n +-> binomial(n-1,(n-1)/2)/(n*2**(n-1)),
x=0,1..,2) \bound{asinx}}
}
```

```
\xctc{
```

When we compute the `\axiom{sin}` of this series, we get `\axiom{x}` (in the sense that all higher terms computed so far are zero).

```
{
```

```
\spadpaste{sin(asinx) \free{asinx}}
```

```
}
```

As we discussed in
[\downlink{‘‘Converting to Power Series’’}](#)
[{ugxProblemSeriesConversionsPage}](#) in Section
 8.9.5 [\ignore{ugxProblemSeriesConversions}](#),
 you can also use the operations [\axiomFun{taylor}](#), [\axiomFun{laurent}](#) and
[\axiomFun{puiseux}](#) instead of [\axiomFun{series}](#) if you know ahead of time
 what kind of exponents a series has.
 You can’t go wrong using [\axiomFun{series}](#), though.

12.0.171 Substituting Numerical Values in Power Series

<ug08.ht>+≡

```
\begin{page}{ugxProblemSeriesSubstitutePage}
{8.9.7. Substituting Numerical Values in Power Series}
\beginscroll
```

Use `\axiomFunFrom{eval}{UnivariatePowerSeriesCategory}`
to substitute a numerical value for a variable in
a power series.
For example, here's a way to obtain numerical approximations of
`\axiom{\%e}` from the Taylor series
expansion of `\axiom{exp(x)}`.

```
\labelSpace{1pc}
\xtc{
First you create the desired Taylor expansion.
}{
\spadpaste{f := taylor(exp(x)) \bound{f}}
}
\xtc{
Then you evaluate the series at the value \axiom{1.0}.
The result is a sequence of the partial sums.
}{
\spadpaste{eval(f,1.0)}
}
```

```

12.0.172 Example: Bernoulli Polynomials and Sums of Powers

ug08.ht +=

```
\begin{page}{ugxProblemSeriesBernoulliPage}
{8.9.8. Example: Bernoulli Polynomials and Sums of Powers}
\beginscroll
```

Axiom provides operations for computing definite and indefinite sums.

```
\labelSpace{3pc}
\xtc{
You can compute the sum of the first
ten fourth powers by evaluating this.
This creates a list whose entries are
\texht{$m^4$}{\axiom{m**4}} as \texht{$m$}{\axiom{m}} ranges from 1
to 10, and then computes the sum of the entries of that list.
}{
\spadpaste{reduce(+,[m**4 for m in 1..10])}
}
\xtc{
You can also compute a formula for the sum of the first
\texht{$k$}{\axiom{k}} fourth powers, where \texht{$k$}{\axiom{k}} is an
unspecified positive integer.
}{
\spadpaste{sum4 := sum(m**4, m = 1..k) \bound{sum4}}
}
\xtc{
This formula is valid for any positive integer \texht{$k$}{\axiom{k}}.
For instance, if we replace \texht{$k$}{\axiom{k}} by 10,
we obtain the number we computed earlier.
}{
\spadpaste{eval(sum4, k = 10) \free{sum4}}
}
```

You can compute a formula for the sum of the first $\texht{k}{\axiom{k}}$ $\texht{n}{\axiom{n}}$ powers in a similar fashion. Just replace the $\texht{4}{\axiom{4}}$ in the definition of $\texht{sum4}{\userfun{sum4}}$ by any expression not involving $\texht{k}{\axiom{k}}$. Axiom computes these formulas using Bernoulli polynomials; we use the rest of this section to describe this method.

```
%
\xtc{
```

```

First consider this function of \axiom{t} and \axiom{x}.
}{
\spadpaste{f := t*exp(x*t) / (exp(t) - 1) \bound{f}}
}
\noOutputXtc{
Since the expressions involved get quite large, we tell
Axiom to show us only terms of degree up to \axiom{5.}
}{
\spadpaste{)set streams calculate 5 \bound{set}}
}
%
%
\xtc{
If we look at the Taylor expansion of \axiom{f(x, t)} about \axiom{t = 0,}
we see that the coefficients of the powers of \axiom{t} are polynomials
in \axiom{x}.
}{
\spadpaste{ff := taylor(f,t = 0) \free{f set} \bound{ff}}
}

```

In fact, the $\text{\eth{\axiom{n}}}$ coefficient in this series is essentially the $\text{\eth{\axiom{n}}}$ Bernoulli polynomial: the $\text{\eth{\axiom{n}}}$ coefficient of the series is $\text{\texht{\$1 \over {n!}} B_n(x)\$}\{\text{\axiom{1/n! * Bn(x)}}\}$, where $\text{\texht{\$B_n(x)\$}}\{\text{\axiom{Bn(x)}}\}$ is the $\text{\eth{\axiom{n}}}$ Bernoulli polynomial. Thus, to obtain the $\text{\eth{\axiom{n}}}$ Bernoulli polynomial, we multiply the $\text{\eth{\axiom{n}}}$ coefficient of the series $\text{\axiom{ff}}$ by $\text{\axiom{n!}}$.

```

\xtc{
For example, the sixth Bernoulli polynomial is this.
}{
\spadpaste{factorial(6) * coefficient(ff,6) \free{ff}}
}
%
\xtc{
We derive some properties of the function \axiom{f(x,t)}.
First we compute \axiom{f(x + 1,t) - f(x,t)}.
}{
\spadpaste{g := eval(f, x = x + 1) - f \bound{g} \free{f}}
}
%
\xtc{
If we normalize \axiom{g}, we see that it has a particularly simple form.
}{
\spadpaste{normalize(g) \free{g}}
}

```

```

}
%
From this it follows that the \eth{\axiom{n}}
coefficient in the Taylor expansion of
\axiom{g(x,t)} at \axiom{t = 0} is
\texht{\${1\over{(n-1)\!}}\!:\!x^{\!n-1}\!}\!{\axiom{1/(n-1)! * x**(n-1)}}.
\xtc{
If you want to check this, evaluate the next expression.
}{
\spadpaste{taylor(g,t = 0) \free{g}}
}
%
However, since \axiom{g(x,t) = f(x+1,t)-f(x,t)}, it follows that the
\eth{\axiom{n}} coefficient is
\texht{\${1\over{n!}}\!:\!(B_n(x+1)-B_n(x))\!}\!{\axiom{1/n! * (Bn(x + 1) -
Bn(x))}}.
Equating coefficients, we see that
\texht{\${1\over{(n-1)\!}}\!:\!x^{\!n-1}\!} = {\!1\over{n!}}\!:\!(B_n(x + 1) -
B_n(x))\!}\!{\axiom{1/(n-1)! * x**(n-1) = 1/n! * (Bn(x + 1) - Bn(x))}}
and, therefore,
\texht{\$x^{\!n-1}\!} = {\!1\over{n}}\!:\!(B_n(x + 1) -
B_n(x))\!}\!{\axiom{x**(n-1) = 1/n * (Bn(x + 1) - Bn(x))}}.
%
Let's apply this formula repeatedly, letting \axiom{x} vary between two
integers \axiom{a} and \axiom{b}, with \axiom{a < b}:
%
\begin{verbatim}
a**(n-1)      = 1/n * (Bn(a + 1) - Bn(a))
(a + 1)**(n-1) = 1/n * (Bn(a + 2) - Bn(a + 1))
(a + 2)**(n-1) = 1/n * (Bn(a + 3) - Bn(a + 2))
.
.
.
(b - 1)**(n-1) = 1/n * (Bn(b) - Bn(b - 1))
b**(n-1)      = 1/n * (Bn(b + 1) - Bn(b))
\end{verbatim}

When we add these equations we find that
the sum of the left-hand sides is
\texht{\$\sum_{m=a}^b m^{\!n-1}\!}\!{\axiom{\sum(m = a..b, m ** (n-1))}},%
the sum of the
\texht{\$(n-1)^{\!{\hbox{\small\rm st}}}\!}\!{\axiom{(n-1)}-st}
powers from \axiom{a} to \axiom{b}.
The sum of the right-hand sides is a ‘‘telescoping series.’’
After cancellation, the sum is simply
\texht{\${1\over{n}}\!:\!(B_n(b + 1) -

```

$B_n(a)$ $\} \{ \backslash \text{axiom} \{ 1/n * (B_n(b + 1) - B_n(a)) \} \}.$

Replacing $\backslash \text{axiom} \{ n \}$ by $\backslash \text{axiom} \{ n + 1 \}$, we have shown that
 $\backslash \text{centerline} \{ \{ \backslash \text{axiom} \{ \text{sum}(m = a..b, m ** n) = 1/(n + 1) * (B_{n+1}(b + 1) - B_{n+1}(a)) \} \} \}$

Let's use this to obtain the formula for the sum of fourth powers.

```
\xctc{
First we obtain the Bernoulli polynomial \texht{$B_5$}\{\axiom{B5}\}.
}{
\spadpaste{B5 := factorial(5) * coefficient(ff,5) \free{ff} \bound{B5}}
}
%
\xctc{
To find the sum of the first \texht{$k$}\{\axiom{k}\} 4th powers,
we multiply \axiom{1/5} by
\texht{$B_5(k+1) - B_5(1)$}\{\axiom{B5(k + 1) - B5(1)}\}.
}{
\spadpaste{1/5 * (eval(B5, x = k + 1) - eval(B5, x = 1)) \free{B5}}
}
%
\xctc{
This is the same formula that we obtained via \axiom{sum(m**4, m = 1..k)}.
}{
\spadpaste{sum4 \free{sum4}}
}
}
```

At this point you may want to do the same computation, but with an exponent other than $\backslash \text{axiom} \{ 4 \}$.

For example, you might try to find a formula for the sum of the first $\texht{\$k\$}\{\backslash \text{axiom} \{ k \} \}$ 20th powers.

\beginscroll
%
In this section we discuss Axiom's facilities for
solving
differential equations in closed-form and in series.

Axiom provides facilities for closed-form solution of
single differential equations of the following kinds:
\indent{4}
\beginitems
\item[-] linear ordinary differential equations, and
\item[-] non-linear first order ordinary differential equations
when integrating factors can be found just by integration.
\enditems
\indent{0}

For a discussion of the solution of systems of linear and polynomial
equations, see
\downlink{‘‘Solution of Linear and Polynomial Equations’’}
{ugProblemLinPolEqnPage} in Section 8.5\ignore{ugProblemLinPolEqn}.

12.0.174 Closed-Form Solutions of Linear Differential Equations

`<ug08.ht>+≡`

```
\begin{page}{ugxProblemLDEQClosedPage}
{8.10.1. Closed-Form Solutions of Linear Differential Equations}
\beginscroll
```

A *differential equation* is an equation involving an unknown *function* and one or more of its derivatives. The equation is called *ordinary* if derivatives with respect to only one dependent variable appear in the equation (it is called *partial* otherwise). The package `\axiomType{ElementaryFunctionODESolver}` provides the top-level operation `\spadfun {solve}` for finding closed-form solutions of ordinary differential equations.

To solve a differential equation, you must first create an operator for the unknown function.

```
%
\xtc{
We let \axiom{y} be the unknown function in terms of \axiom{x}.
}{
```

```
\spadpaste{y := operator 'y \bound{y}}
}
%
```

You then type the equation using `\axiomFun{D}` to create the derivatives of the unknown function `\axiom{y(x)}` where `\axiom{x}` is any symbol you choose (the so-called *dependent variable*).

```
%
\xtc{
This is how you enter
the equation \axiom{y}'' + y' + y = 0.
}{
\spadpaste{deq := D(y x, x, 2) + D(y x, x) + y x = 0\bound{e1}\free{y}}
}
%
```

The simplest way to invoke the `\axiomFun{solve}` command is with three arguments.

```
\begin{items}
\item the differential equation,
\item the operator representing the unknown function,
\item the dependent variable.
\end{items}
```

```
%
\xtc{
So, to solve the above equation, we enter this.
```

```

}{
\spadpaste{solve(deq, y, x) \free{e1}\free{y}}
}
%
Since linear ordinary differential equations have infinitely many
solutions, \axiomFun{solve} returns a {\it particular solution}
\texht{$f_p$}\{\axiom{f_p}\}
and a basis
\texht{$f_1, \dots, f_n$}\{\axiom{f1}, \dots, \axiom{fn}\}
for the solutions of the corresponding homogeneous equation.
Any expression of the form
\texht{$f_p + c_1 f_1 + \dots c_n f_n$}\{\axiom{fp} + c1 f1 + ... + cn fn\}
where the \texht{$c_i$}\{\axiom{ci}\} do not involve
the dependent variable is also a solution.
This is similar to what you get when you solve systems of linear
algebraic equations.

```

A way to select a unique solution is to specify {\it initial conditions}: choose a value \axiom{a} for the dependent variable and specify the values of the unknown function and its derivatives at \axiom{a}.

If the number of initial conditions is equal to the order of the equation, then the solution is unique (if it exists in closed form!) and \axiomFun{solve} tries to find it.

To specify initial conditions to \axiomFun{solve}, use an \axiomType{Equation} of the form \axiom{x = a} for the third parameter instead of the dependent variable, and add a fourth parameter consisting of the list of values \axiom{y(a), y'(a), ...}.

```

\xtc{
To find the solution of \axiom{y'' + y = 0} satisfying \axiom{y(0) =
y'(0) = 1}, do this.
}{
\spadpaste{deq := D(y x, x, 2) + y x \bound{e2}\free{y}}
}
\xtc{
You can omit the \axiom{= 0} when you enter the equation to be solved.
}{
\spadpaste{solve(deq, y, x = 0, [1, 1]) \free{e2}\free{y}}
}
%

```

Axiom is not limited to linear differential equations with constant coefficients. It can also find solutions when the coefficients are rational or algebraic functions of the dependent variable. Furthermore, Axiom is not limited by the order of the equation.

```

\xtc{
Axiom can solve the following third order equations with
polynomial coefficients.
}{
\spadpaste{deq := x**3 * D(y x, x, 3) + x**2 * D(y x, x, 2) - 2 *
x * D(y x, x) + 2 * y x = 2 * x**4 \bound{e3}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{e3}\free{y}}
}
%
%
\xtc{
Here we are solving a homogeneous equation.
}{
\spadpaste{deq := (x**9+x**3) * D(y x, x, 3) + 18 * x**8 *
D(y x, x, 2) - 90 * x * D(y x, x) - 30 * (11 * x**6 - 3) * y x
\bound{e4}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{e4}\free{y}}
}

```

On the other hand, and in contrast with the operation `\axiomFun{integrate}`, it can happen that Axiom finds no solution and that some closed-form solution still exists. While it is mathematically complicated to describe exactly when the solutions are guaranteed to be found, the following statements are correct and form good guidelines for linear ordinary differential equations:

```

\begin{items}
\item If the coefficients are constants, Axiom finds a complete basis
of solutions (i.e, all solutions).
\item If the coefficients are rational functions in the dependent variable,
Axiom at least finds all solutions that do not involve algebraic
functions.
\end{items}
%
Note that this last statement does not mean that Axiom does not find
the solutions that are algebraic functions.
It means that it is not
guaranteed that the algebraic function solutions will be found.
%

```

```

\xtc{
This is an example where all the algebraic solutions are found.
}{
\spadpaste{deq := (x**2 + 1) * D(y x, x, 2) + 3 * x *
D(y x, x) + y x = 0 \bound{e5}\free{y}}
}
\xtc{
}{
\spadpaste{solve(deq, y, x) \free{e5}\free{y}}
}

12.0.175 Closed-Form Solutions of Non-Linear DEs

<ug08.ht>+≡

```
\begin{page}{ugxProblemNLDEQClosedPage}
{8.10.2. Closed-Form Solutions of Non-Linear DEs}
\beginscroll
```

This is an example that shows how to solve a non-linear first order ordinary differential equation manually when an integrating factor can be found just by integration.
At the end, we show you how to solve it directly.

Let's solve the differential equation $\text{\axiom}\{y' = y / (x + y \log y)\}$.

```
%
\xtc{
Using the notation
\axiom{m(x, y) + n(x, y) y' = 0},
we have \axiom{m = -y} and \axiom{n = x + y log y}.
}{
\spadpaste{m := -y \bound{m}}
}
\xtc{
}{
\spadpaste{n := x + y * log y \bound{n}}
}
%
\xtc{
We first check for exactness, that is, does \axiom{dm/dy = dn/dx}?
}{
\spadpaste{D(m, y) - D(n, x) \free{m n}}
}
%
This is not zero, so the equation is not exact.
Therefore we must look for
an integrating factor: a function \axiom{mu(x,y)} such that
\axiom{d(mu m)/dy = d(mu n)/dx}.
Normally, we first search for \axiom{mu(x,y)} depending only on
\axiom{x} or only on \axiom{y}.
%
\xtc{
Let's search for such a \axiom{mu(x)} first.
}{
\spadpaste{mu := operator 'mu \bound{mu}}
}
\xtc{
}{
```

```

\spadpaste{a := D(mu(x) * m, y) - D(mu(x) * n, x) \bound{a}\free{m n mu}}
}
%
%
\xtc{
If the above is zero for a function
\axiom{mu} that does {\it not} depend on \axiom{y}, then
\axiom{mu(x)} is an integrating factor.
}{
\spadpaste{solve(a = 0, mu, x) \free{mu a}}
}
%
The solution depends on \axiom{y}, so there is no integrating
factor that depends on \axiom{x} only.
%
\xtc{
Let's look for one that depends on \axiom{y} only.
}{
\spadpaste{b := D(mu(y) * m, y) - D(mu(y) * n, x) \bound{b}\free{mu m}}
}
\xtc{
}{
\spadpaste{sb := solve(b = 0, mu, y) \free{mu b}\bound{sb}}
}
\noindent
We've found one!
%
\xtc{
The above \axiom{mu(y)} is an integrating factor.
We must multiply our initial equation
(that is, \axiom{m} and \axiom{n}) by the integrating factor.
}{
\spadpaste{intFactor := sb.basis.1 \bound{intFactor}\free{sb}}
}
\xtc{
}{
\spadpaste{m := intFactor * m \bound{m1}\free{m intFactor}}
}
\xtc{
}{
\spadpaste{n := intFactor * n \bound{n1}\free{n intFactor}}
}
%
\xtc{
Let's check for exactness.
}{

```

```

\spadpaste{D(m, y) - D(n, x) \free{m1 n1}}
}
%
We must solve the exact equation, that is, find a function
\axiom{s(x,y)} such that
\axiom{ds/dx = m} and \axiom{ds/dy = n}.
%
\xtc{
We start by writing \axiom{s(x, y) = h(y) + integrate(m, x)}
where \axiom{h(y)} is an unknown function of \axiom{y}.
This guarantees that \axiom{ds/dx = m}.
}{
\spadpaste{h := operator 'h \bound{h}}
}
\xtc{
}{
\spadpaste{sol := h y + integrate(m, x) \bound{sol}\free{h m1}}
}
%
%
\xtc{
All we want is to find \axiom{h(y)} such that
\axiom{ds/dy = n}.
}{
\spadpaste{dsol := D(sol, y) \free{sol}\bound{dsol}}
}
\xtc{
}{
\spadpaste{nsol := solve(dsol = n, h, y) \free{dsol n1 h}\bound{nsol}}
}
%
\xtc{
The above particular solution is the \axiom{h(y)} we want, so we just
replace \axiom{h(y)} by it in the implicit solution.
}{
\spadpaste{eval(sol, h y = nsol.particular) \free{sol h nsol}}
}
%
A first integral of the initial equation is obtained by setting
this result equal to an arbitrary constant.

Now that we've seen how to solve the equation "by hand,"
we show you how to do it with the \axiomFun{solve} operation.
\xtc{
First define \axiom{y} to be an operator.
}{

```

```

\spadpaste{y := operator 'y \bound{y}}
}
\xtc{
Next we create the differential equation.
}{
\spadpaste{deq := D(y x, x) = y(x) / (x + y(x) * log y x)
\bound{deq}\free{y}}
}
\xtc{
Finally, we solve it.
}{
\spadpaste{solve(deq, y, x) \free{deq y}}
}

12.0.176 Power Series Solutions of Differential Equations

(ug08.ht)+≡

```
\begin{page}{ugxProblemDEQSeriesPage}
{8.10.3. Power Series Solutions of Differential Equations}
\beginscroll
```

The command to solve differential equations in power series around a particular initial point with specific initial conditions is called `\axiomFun{seriesSolve}`. It can take a variety of parameters, so we illustrate its use with some examples.

```
\labelSpace{1pc}
\noOutputXtc{
Since the coefficients of some solutions
are quite large, we reset the default to compute only seven terms.
}{
\spadpaste{)set streams calculate 7 \bound{c7}}
}
```

You can solve a single nonlinear equation of any order. For example, we solve `\axiom{y''' = sin(y'') * exp(y) + cos(x)}` subject to `\axiom{y(0) = 1, y'(0) = 0, y''(0) = 0}`.

```
\xctc{
We first tell Axiom
that the symbol \axiom{y} denotes a new operator.
}{
\spadpaste{y := operator 'y \bound{y}}
}
\xctc{
Enter the differential equation using \axiom{y} like any system
function.
}{
\spadpaste{eq := D(y(x), x, 3) - sin(D(y(x), x, 2))*exp(y(x)) =
cos(x)\bound{eq}\free{y}}
}
%
\xctc{
Solve it around \axiom{x = 0} with the initial conditions
\axiom{y(0) = 1, y'(0) = y''(0) = 0}.
}{
\spadpaste{seriesSolve(eq, y, x = 0, [1, 0, 0])\free{y}\free{eq}\free{c7}}
```

```
}
```

You can also solve a system of nonlinear first order equations. For example, we solve a system that has `\axiom{tan(t)}` and `\axiom{sec(t)}` as solutions.

```
\xctc{
We tell Axiom that \axiom{x} is also an operator.
}{
\spadpaste{x := operator 'x\bound{x}}
}
\xctc{
Enter the two equations forming our system.
}{
\spadpaste{eq1 := D(x(t), t) = 1 + x(t)**2\free{x}\free{y}\bound{eq1}}
}
%
\xctc{
}{
\spadpaste{eq2 := D(y(t), t) = x(t) * y(t)\free{x}\free{y}\bound{eq2}}
}
%
\xctc{
Solve the system around \axiom{t = 0} with the initial conditions
\axiom{x(0) = 0} and \axiom{y(0) = 1}.
Notice that since we give the unknowns in the
order \axiom{[x, y]}, the answer is a list of two series in the order
\axiom{[series for x(t), series for y(t)]}.
}{
\spadpaste{seriesSolve([eq2, eq1], [x, y], t = 0,
[y(0) = 1, x(0) = 0])\free{x}\free{y}\free{eq1}\free{eq2}\free{c7}}
}
\noindent
The order in which we give the
equations and the initial conditions has no effect on the order of
the solution.

\begin{page}{ugProblemFinitePage}{8.11. Finite Fields}
\begin{scroll

```

A $\{\text{finite field}\}$ (also called a $\{\text{Galois field}\}$) is a finite algebraic structure where one can add, multiply and divide under the same laws (for example, commutativity, associativity or distributivity) as apply to the rational, real or complex numbers.

Unlike those three fields, for any finite field there exists a positive prime integer p , called the `\axiomFun{characteristic}`, such that `\texht{$p \mid x = 0$}``{\axiom{p * x = 0}}` for any element x in the finite field. In fact, the number of elements in a finite field is a power of the characteristic and for each prime p and positive integer n there exists exactly one finite field with `\texht{p^n}``{\axiom{p**n}}` elements, up to isomorphism.^{\footnote{For more information about the algebraic structure and properties of finite fields, see, for example, S. Lang, *{\it Algebra}*, Second Edition, New York: Addison-Wesley Publishing Company, Inc., 1984, ISBN 0 201 05487 6; or R. Lidl, H. Niederreiter, *{\it Finite Fields}*, Encyclopedia of Mathematics and Its Applications, Vol. 20, Cambridge: Cambridge Univ. Press, 1983, ISBN 0 521 30240 4.}}

When `\axiom{n = 1,}` the field has p elements and is called a *{\it prime field}*, discussed in `\texht{the next section}`{

`\downlink{'Modular Arithmetic and Prime Fields'}`
`{ugxProblemFinitePrimePage}`
 in Section 8.11.1`\ignore{ugxProblemFinitePrime}}`.

There are several ways of implementing extensions of finite fields, and Axiom provides quite a bit of freedom to allow you to choose the one that is best for your application. Moreover, we provide operations for converting among the different representations of extensions and different extensions of a single field.

Finally, note that you usually need to package-call operations from finite fields if the operations do not take as an argument an object of the field.

See `\downlink{'Package Calling and Target Types'}`
`{ugTypesPkgCallPage}` in Section 2.9`\ignore{ugTypesPkgCall}` for more information on package-calling.

12.0.178 Modular Arithmetic and Prime Fields

<ug08.ht>+≡

```
\begin{page}{ugxProblemFinitePrimePage}
{8.11.1. Modular Arithmetic and Prime Fields}
\beginscroll
```

Let \smath{n} be a positive integer.

It is well known that you can get the same result if you perform addition, subtraction or multiplication of integers and then take the remainder on dividing by \smath{n} as if you had first done such remaindering on the operands, performed the arithmetic and then (if necessary) done remaindering again.

This allows us to speak of arithmetic

$\{it modulo\} \smath{n}$ or, more simply

$\{it mod\} \smath{n}$.

```
\xctc{
```

In Axiom, you use $\axiomType{IntegerMod}$ to do such arithmetic.

```
}{
```

```
\spadpaste{(a,b) : IntegerMod 12 \bound{abdec}}
```

```
}
```

```
\xctc{
```

```
}{
```

```
\spadpaste{(a, b) := (16, 7) \free{abdec}\bound{a b}}
```

```
}
```

```
\xctc{
```

```
}{
```

```
\spadpaste{[a - b, a * b] \free{a b}}
```

```
}
```

```
\xctc{
```

If \smath{n} is not prime, there is only a limited notion of reciprocals and division.

```
}{
```

```
\spadpaste{a / b \free{a b}}
```

```
}
```

```
\xctc{
```

```
}{
```

```
\spadpaste{recip a \free{a}}
```

```
}
```

```
\xctc{
```

Here $\axiom{7}$ and $\axiom{12}$ are relatively prime, so $\axiom{7}$ has a multiplicative inverse modulo $\axiom{12}$.

```
}{
```

```
\spadpaste{recip b \free{b}}
```

```
}
```

If we take $\text{\smath{n}}$ to be a prime number $\text{\smath{p}}$, then taking inverses and, therefore, division are generally defined.

`\xctc{`

Use `\axiomType{PrimeField}` instead of `\axiomType{IntegerMod}` for $\text{\smath{n}}$ prime.

`{`

`\spadpaste{c : PrimeField 11 := 8 \bound{c}}`

`}`

`\xctc{`

`{`

`\spadpaste{inv c \free{c}}`

`}`

`\xctc{`

You can also use `\axiom{1/c}` and `\axiom{c**(-1)}` for the inverse of $\text{\smath{c}}$.

`{`

`\spadpaste{9/c \free{c}}`

`}`

`\axiomType{PrimeField}` (abbreviation `\axiomType{PF}`) checks if its argument is prime when you try to use an operation from it.

If you know the argument is prime (particularly if it is large),

`\axiomType{InnerPrimeField}` (abbreviation `\axiomType{IPF}`) assumes the argument has already been verified to be prime.

If you do use a number that is not prime, you will eventually get an error message, most likely a division by zero message.

For computer science applications, the most important finite fields are `\axiomType{PrimeField 2}` and its extensions.

`\xctc{`

In the following examples, we work with the finite field with $\text{\smath{p} = 101}$ elements.

`{`

`\spadpaste{GF101 := PF 101 \bound{GF101} }`

`}`

`\xctc{`

Like many domains in Axiom, finite fields provide an operation for returning a random element of the domain.

`{`

`\spadpaste{x := random()\$GF101 \bound{x}\free{GF101}}`

`}`

`\xctc{`

`{`

`\spadpaste{y : GF101 := 37 \bound{y}\free{GF101}}`

`}`

`\xctc{`

```

}{
\spadpaste{z := x/y \bound{z}\free{x y}}
}
\xtc{
}{
\spadpaste{z * y - x \free{x y z}}
}
%
\xtc{
The element \axiom{2} is a {\it primitive element} of this field,
}{
\spadpaste{pe := primitiveElement()\$GF101 \bound{pe}\free{GF101}}
}
%
\xtc{
in the sense that its powers enumerate all nonzero elements.
}{
\spadpaste{[pe**i for i in 0..99] \free{pe}}
}
%
%
\xtc{
If every nonzero element is a power of a primitive element, how do you
determine what the exponent is?
Use
\axiomFun{discreteLog}.
}{
\spadpaste{ex := discreteLog(y) \bound{ex}\free{y}}
}
\xtc{
}{
\spadpaste{pe ** ex \free{ex pe}}
}
%
\xtc{
The \axiomFun{order} of a nonzero element \smath{x} is the
smallest positive integer \smath{t} such
\texht{\$x^t = 1\$}\{\axiom{x**t = 1}\}.
}{
\spadpaste{order y \free{y}}
}
\xtc{
The order of a primitive element is the defining \smath{p-1}.
}{
\spadpaste{order pe \free{pe}}
}
}

12.0.179 Extensions of Finite Fields

<ug08.ht>+≡

```
\begin{page}{ugxProblemFiniteExtensionFinitePage}
{8.11.2. Extensions of Finite Fields}
\beginscroll
```

When you want to work with an extension of a finite field in Axiom, you have three choices to make:

```
\indent{4}
\beginitems
\item[1. ] Do you want to generate an extension of the prime field
(for example, \axiomType{PrimeField 2}) or an extension of a given field?
%
\item[2. ] Do you want to use a representation that is particularly
efficient for multiplication, exponentiation and addition but
uses a lot of computer memory (a representation that models the cyclic
group structure of the multiplicative group of the field extension
and uses a Zech logarithm table), one that
uses a normal basis for the vector space structure of the field
extension, or one that performs arithmetic modulo an irreducible
polynomial?
The cyclic group representation is only usable up to ‘‘medium’’
(relative to your machine’s performance)
sized fields.
If the field is large and the normal basis is relatively simple,
the normal basis representation is more efficient for exponentiation than
the irreducible polynomial representation.
%
\item[3. ] Do you want to provide a polynomial explicitly, a root of which
‘‘generates’’ the extension in one of the three senses in (2),
or do you wish to have the polynomial generated for you?
\enditems
\indent{0}
```

This illustrates one of the most important features of Axiom: you can choose exactly the right data-type and representation to suit your application best.

We first tell you what domain constructors to use for each case above, and then give some examples.

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that automatically generate extensions of the prime field:
\newline
\axiomType{FiniteField} \newline
```

```
\axiomType{FiniteFieldCyclicGroup} \newline
\axiomType{FiniteFieldNormalBasis}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that generate extensions of an arbitrary field:
\newline
\axiomType{FiniteFieldExtension} \newline
\axiomType{FiniteFieldExtensionByPolynomial} \newline
\axiomType{FiniteFieldCyclicGroupExtension} \newline
\axiomType{FiniteFieldCyclicGroupExtensionByPolynomial} \newline
\axiomType{FiniteFieldNormalBasisExtension} \newline
\axiomType{FiniteFieldNormalBasisExtensionByPolynomial}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that use a cyclic group representation:
\newline
\axiomType{FiniteFieldCyclicGroup} \newline
\axiomType{FiniteFieldCyclicGroupExtension} \newline
\axiomType{FiniteFieldCyclicGroupExtensionByPolynomial}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that use a normal basis representation:
\newline
\axiomType{FiniteFieldNormalBasis} \newline
\axiomType{FiniteFieldNormalBasisExtension} \newline
\axiomType{FiniteFieldNormalBasisExtensionByPolynomial}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that use an irreducible modulus polynomial representation:
\newline
\axiomType{FiniteField} \newline
\axiomType{FiniteFieldExtension} \newline
\axiomType{FiniteFieldExtensionByPolynomial}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors that generate a polynomial for you:
\newline
\axiomType{FiniteField} \newline
\axiomType{FiniteFieldExtension} \newline
\axiomType{FiniteFieldCyclicGroup} \newline
\axiomType{FiniteFieldCyclicGroupExtension} \newline
\axiomType{FiniteFieldNormalBasis} \newline
\axiomType{FiniteFieldNormalBasisExtension}
```

```
\texht{\hangafter=1\hangindent=2pc}{\noindent}
Constructors for which you provide a polynomial:
```

```

\newline
\axiomType{FiniteFieldExtensionByPolynomial} \newline
\axiomType{FiniteFieldCyclicGroupExtensionByPolynomial} \newline
\axiomType{FiniteFieldNormalBasisExtensionByPolynomial}

```

These constructors are discussed in the following sections where we collect together descriptions of extension fields that have the same underlying representation.\footnote{For more information on the implementation aspects of finite fields, see

J. Grabmeier, A. Scheerhorn, {\it Finite Fields in AXIOM,} Technical Report, IBM Heidelberg Scientific Center, 1992.}

If you don't really care about all this detail, just use `\axiomType{FiniteField}`.

As your knowledge of your application and its Axiom implementation grows, you can come back and choose an alternative constructor that may improve the efficiency of your code.

Note that the exported operations are almost the same for all constructors of finite field extensions and include the operations exported by `\axiomType{PrimeField}`.

12.0.180 Irreducible Mod Polynomial Representations

⇒ “notitle” (ugxProblemFiniteExtensionFinitePage) 12.0.179 on page 2533

`<ug08.ht>+≡`

```
\begin{page}{ugxProblemFiniteModulusPage}
{8.11.3. Irreducible Mod Polynomial Representations}
\beginscroll
```

All finite field extension constructors discussed in this section use a representation that performs arithmetic with univariate (one-variable) polynomials modulo an irreducible polynomial. This polynomial may be given explicitly by you or automatically generated.

The ground field may be the prime field or one you specify.

See

```
\downlink{‘‘Extensions of Finite Fields’’}
{ugxProblemFiniteExtensionFinitePage} in Section 8.11.2
\ignore{ugxProblemFiniteExtensionFinite}
for general information about finite field extensions.
```

For `\axiomType{FiniteField}` (abbreviation `\axiomType{FF}`) you provide a prime number `\smath{p}` and an extension degree `\smath{n}`.

This degree can be 1.

```
%
\xtc{
Axiom uses the prime field \axiomType{PrimeField(p)},
here \axiomType{PrimeField 2},
and it chooses an irreducible polynomial of degree \smath{n},
here 12, over the ground field.
}{
\spadpaste{GF4096 := FF(2,12); \bound{GF4096}}
}
%
```

The objects in the generated field extension are polynomials of degree at most `\smath{n-1}` with coefficients in the prime field.

The polynomial indeterminate is automatically chosen by Axiom and is typically something like `\axiom{\%A}` or `\axiom{\%D}`.

These (strange) variables are `{\it only}` for output display; there are several ways to construct elements of this field.

The operation `\axiomFun{index}` enumerates the elements of the field

```

extension and accepts as argument the integers from 1 to
\smath{p \texht{^}{**} n}.
%
\xtc{
The expression
\axiom{index(p)} always gives the indeterminate.
}{
\spadpaste{a := index(2)\$GF4096 \bound{a}\free{GF4096}}
}
%
%
\xtc{
You can build polynomials in \smath{a} and calculate in
\axiom{GF4096}.
}{
\spadpaste{b := a**12 - a**5 + a \bound{b}\free{a}}
}
\xtc{
}{
\spadpaste{b ** 1000 \free{b}}
}
\xtc{
}{
\spadpaste{c := a/b \free{a b}\bound{c}}
}
%
\xtc{
Among the available operations are \axiomFun{norm} and \axiomFun{trace}.
}{
\spadpaste{norm c \free{c}}
}
\xtc{
}{
\spadpaste{trace c \free{c}}
}
%
%

```

Since any nonzero element is a power of a primitive element, how do we discover what the exponent is?

```

%
\xtc{
The operation \axiomFun{discreteLog} calculates
the exponent and,
if it is called with only one argument, always refers to the primitive
element returned by \axiomFun{primitiveElement}.

```

```

}{
\spadpaste{dL := discreteLog a \free{a}\bound{dL}}
}
\xtc{
}{
\spadpaste{g ** dL \free{dL g}}
}

```

`\axiomType{FiniteFieldExtension}` (abbreviation `\axiomType{FFX}`) is similar to `\axiomType{FiniteField}` except that the ground-field for `\axiomType{FiniteFieldExtension}` is arbitrary and chosen by you.

```

%
\xtc{
In case you select the prime field as ground field, there is
essentially no difference between the constructed two finite field
extensions.

```

```

}{
\spadpaste{GF16 := FF(2,4); \bound{GF16}}
}
\xtc{
}{
\spadpaste{GF4096 := FFX(GF16,3); \bound{GF4096x}\free{GF16}}
}
\xtc{
}{
\spadpaste{r := (random()\$GF4096) ** 20 \free{GF4096x}\bound{r}}
}
\xtc{
}{
\spadpaste{norm(r) \free{r}}
}
%

```

`\axiomType{FiniteFieldExtensionByPolynomial}` (abbreviation `\axiomType{FFP}`) is similar to `\axiomType{FiniteField}` and `\axiomType{FiniteFieldExtension}` but is more general.

```

%
\xtc{
}{
\spadpaste{GF4 := FF(2,2); \bound{GF4}}
}
\xtc{
}{
\spadpaste{f := nextIrreduciblePoly(random(6)\$FFPOLY(GF4))\$FFPOLY(GF4)
\free{GF4}\bound{f}}
}

```

```

}
\xtc{
For \axiomType{FFP} you choose both the
ground field and the irreducible polynomial used in the representation.
The degree of the extension is the degree of the polynomial.
}{
\spadpaste{GF4096 := FFP(GF4,f); \bound{GF4096y}\free{f GF4}}
}
\xtc{
}{
\spadpaste{discreteLog random()\$GF4096 \free{GF4096y}}
}
%

12.0.181 Cyclic Group Representations

⇒ “notitle” (ugxProblemFiniteUtilityPage) 12.0.184 on page 2572

```

<ug08.ht>+≡
\begin{page}{ugxProblemFiniteCyclicPage}
{8.11.4. Cyclic Group Representations}
\beginscroll

```

In every finite field there exist elements whose powers are all the nonzero elements of the field.

Such an element is called a *primitive element*.

In `\axiomType{FiniteFieldCyclicGroup}` (abbreviation `\axiomType{FFCG}`) the nonzero elements are represented by the powers of a fixed primitive element of the field (that is, a generator of its cyclic multiplicative group). Multiplication (and hence exponentiation) using this representation is easy. To do addition, we consider our primitive element as the root of a primitive polynomial (an irreducible polynomial whose roots are all primitive). See `\downlink{‘Utility Operations for Finite Fields’}` `{ugxProblemFiniteUtilityPage}` in Section 8.11.7 `\ignore{ugxProblemFiniteUtility}` for examples of how to compute such a polynomial.

```

%
\xtc{
To use \axiomType{FiniteFieldCyclicGroup} you provide a prime number and an
extension degree.
}{
\spadpaste{GF81 := FFCG(3,4); \bound{GF81}}
}
%
%
\xtc{
Axiom uses the prime field, here \axiomType{PrimeField 3}, as the
ground field and it chooses a primitive polynomial of degree
\smath{n}, here 4, over the prime field.
}{
\spadpaste{a := primitiveElement()\$GF81 \bound{a}\free{GF81}}
}
%
%
\xtc{
You can calculate in \axiom{GF81}.

```

```

}{
\spadpaste{b := a**12 - a**5 + a \bound{b}\free{a}}
}
%
\xtc{
In this representation of finite fields the discrete logarithm
of an element can be seen directly in its output form.
}{
\spadpaste{b \free{b}}
}
\xtc{
}{
\spadpaste{discreteLog b \free{b}}
}
%

\axiomType{FiniteFieldCyclicGroupExtension} (abbreviation
\axiomType{FFCGX}) is similar to \axiomType{FiniteFieldCyclicGroup}
except that the ground field for
\axiomType{FiniteFieldCyclicGroupExtension} is arbitrary and chosen
by you.
In case you select the prime field as ground field, there is
essentially no difference between the constructed two finite field
extensions.
%
\xtc{
}{
\spadpaste{GF9 := FF(3,2); \bound{GF9}}
}
\xtc{
}{
\spadpaste{GF729 := FFCGX(GF9,3); \bound{GF729}\free{GF9}}
}
\xtc{

12.0.182 Normal Basis Representations

⇒ “notitle” (ugxProblemFiniteUtilityPage) 12.0.184 on page 2572

`<ug08.ht>+≡`

```
\begin{page}{ugxProblemFiniteNormalPage}
{8.11.5. Normal Basis Representations}
\beginscroll
```

Let K be a finite extension of degree n of the finite field F and let F have q elements.

An element x of K is said to be

normal over F if the elements

```
\centerline{{\axiom{1, x**q, x**(q**2), ..., x**(q**(n-1))}}}
```

form a basis of K as a vector space over F .

Such a basis is called a *normal basis*.^{\footnote{This agrees with the general definition of a normal basis because the}

n distinct powers of the automorphism

```
\texht{$x \mapsto x^q$}{\axiom{x +-> x**q}}
```

constitute the Galois group of $\mathsf{K/F}$.

If x is normal over F , its minimal

polynomial is also said to be *normal* over F .

There exist normal bases for all finite extensions of arbitrary finite fields.

In `\axiomType{FiniteFieldNormalBasis}` (abbreviation `\axiomType{FFNB}`), the elements of the finite field are represented by coordinate vectors with respect to a normal basis.

```
\xtc{
```

You provide a prime p and an extension degree n .

```
{
```

```
\spadpaste{K := FFNB(3,8) \bound{K}}
```

```
}
```

Axiom uses the prime field `\axiomType{PrimeField(p)}`, here `\axiomType{PrimeField 3}`, and it chooses a normal polynomial of degree n , here 8, over the ground field. The remainder class of the indeterminate is used as the normal element. The polynomial indeterminate is automatically chosen by Axiom and is typically something like `\axiom{\%A}` or `\axiom{\%D}`. These (strange) variables are only for output display; there are several ways to construct

elements of this field. The output of the basis elements is something like

```
\texht{$\%A^{q^i}.$}{
\begin{verbatim}
    i
    q
    %A .
\end{verbatim}
}
%
\xtc{
}{
\spadpaste{a := normalElement()\$K \bound{a}\free{K}}
}
%
%
\xtc{
You can calculate in \smath{K} using \smath{a}.
}{
\spadpaste{b := a**12 - a**5 + a \bound{b}\free{a}}
}
```

\axiomType{FiniteFieldNormalBasisExtension}
(abbreviation \axiomType{FFNBX}) is similar to
\axiomType{FiniteFieldNormalBasis}
except that the groundfield for
\axiomType{FiniteFieldNormalBasisExtension} is arbitrary and chosen
by you. In case you select the prime field as ground field, there
is essentially no difference between the constructed two finite field
extensions.

```
\xtc{
}{
\spadpaste{GF9 := FFNB(3,2); \bound{GF9}}
}
\xtc{
}{
\spadpaste{GF729 := FFNBX(GF9,3); \bound{GF729}\free{GF9}}
}
\xtc{
}{
\spadpaste{r := random()\$GF729 \bound{r}\free{GF729}}
}
\xtc{
}{
\spadpaste{r + r**3 + r**9 + r**27 \free{r}}
```

```

}

\axiomType{FiniteFieldNormalBasisExtensionByPolynomial}
(abbreviation \axiomType{FFNBP}) is similar to
\axiomType{FiniteFieldNormalBasis} and
\axiomType{FiniteFieldNormalBasisExtension} but is more general.
For \axiomType{FiniteFieldNormalBasisExtensionByPolynomial} you
choose both the ground field and the irreducible polynomial used
in the representation.
The degree of the extension is the degree of the polynomial.

%
\xtc{
}{
\spadpaste{GF3 := PrimeField 3; \bound{GF3}}
}
\xtc{
We use a utility operation to generate an irreducible normal
polynomial (see
\downlink{'Utility Operations for Finite Fields'}
{ugxProblemFiniteUtilityPage}
in Section 8.11.7\ignore{ugxProblemFiniteUtility}).
The polynomial has one variable that is 'anonymous': it displays
as a question mark.
}{
\spadpaste{f := createNormalPoly(4)\$FFPOLY(GF3) \free{GF3}\bound{f}}
}
\xtc{
}{
\spadpaste{GF81 := FFNBP(GF3,f); \bound{GF81}\free{f GF3}}
}
\xtc{
Let's look at a random element from this field.
}{
\spadpaste{r := random()\$GF81 \free{GF81}\bound{r1}}
}
\xtc{
}{
\spadpaste{r * r**3 * r**9 * r**27 \free{r1}}
}
\xtc{
}{
\spadpaste{norm r \free{r1}}
}

\endscroll

```

\begin{page}{ugxProblemFiniteConversionPage}
{8.11.6. Conversion Operations for Finite Fields}
\beginscroll

\labelSpace{5pc}
%
\xtc{
Let \texht{${K}$}{\axiom{K}} be a finite field.
}{
\spadpaste{K := PrimeField 3 \bound{K}}
}
%
An extension field \texht{${K}_m$}{\axiom{Km}} of degree
\smath{m} over \texht{${K}$}{\axiom{K}} is a subfield of an
extension field \texht{${K}_n$}{\axiom{Kn}} of degree \smath{n}
over \texht{${K}$}{\axiom{K}} if and only if \smath{m} divides
\smath{n}.
\texht{
\centerline{{\begin{tabular}{ccc}}}
\centerline{{${K}_n$ }}}
\centerline{{${}$|${}$ }}
\centerline{{${K}_m$ } & $\Longleftarrow$ & ${}$|${}$ }}
\centerline{{${}$|${}$ }}
\centerline{{K}}
\centerline{{\end{tabular}}}}
}{
\begin{verbatim}
Kn
|
Km  <==>  m | n
|
K
\end{verbatim}
}
\axiomType{FiniteFieldHomomorphisms} provides conversion operations
between different extensions of one
fixed finite ground field and between different representations of
these finite fields.
\xtc{
Let's choose \smath{m} and \smath{n},

```

```

}{
\spadpaste{(m,n) := (4,8) \bound{m n}}
}
\xtc{
build the field extensions,
}{
\spadpaste{Km := FiniteFieldExtension(K,m) \bound{Km}\free{K m}}
}
\xtc{
and pick two random elements from the smaller field.
}{
\spadpaste{Kn := FiniteFieldExtension(K,n) \bound{Kn}\free{K n}}
}
\xtc{
}{
\spadpaste{a1 := random()\$Km \bound{a1}\free{Km}}
}
\xtc{
}{
\spadpaste{b1 := random()\$Km \bound{b1}\free{Km}}
}
%
\xtc{
Since \smath{m} divides \smath{n},
\texht{\$K_m\$}\axiom{Km} is a subfield of \texht{\$K_n\$}\axiom{Kn}.
}{
\spadpaste{a2 := a1 :: Kn \bound{a2}\free{a1 Kn}}
}
\xtc{
Therefore we can convert the elements of \texht{\$K_m\$}\axiom{Km}
into elements of \texht{\$K_n\$}\axiom{Kn}.
}{
\spadpaste{b2 := b1 :: Kn \bound{b2}\free{b1 Kn}}
}
%
%
\xtc{
To check this, let's do some arithmetic.
}{
\spadpaste{a1+b1 - ((a2+b2) :: Km) \free{a1 a2 b1 b2 Km Kn}}
}
\xtc{
}{
\spadpaste{a1*b1 - ((a2*b2) :: Km) \free{a1 a2 b1 b2 Km Kn}}
}
%

```

For example let's choose $\text{\texttt{\textbackslash texht}\text{\textbackslash K_m}}\text{\textbackslash \textbackslash axiom\{Km\}}$ where the representation is 0 plus the cyclic multiplicative group and $\text{\texttt{\textbackslash texht}\text{\textbackslash K_n}}\text{\textbackslash \textbackslash axiom\{Kn\}}$ with a normal basis representation.

12.0.184 Utility Operations for Finite Fields

```

<ug08.ht>+≡
\begin{page}{ugxProblemFiniteUtilityPage}
{8.11.7. Utility Operations for Finite Fields}
\beginscroll

\axiomType{FiniteFieldPolynomialPackage} (abbreviation
\axiomType{FFPOLY})
provides operations for generating, counting and testing polynomials
over finite fields. Let's start with a couple of definitions:
\indent{4}
\beginitems
\item[-] A polynomial is {\it primitive} if its roots are primitive
elements in an extension of the coefficient field of degree equal
to the degree of the polynomial.
\item[-] A polynomial is {\it normal} over its coefficient field
if its roots are linearly independent
elements in an extension of the coefficient field of degree equal
to the degree of the polynomial.
\enditems
\indent{0}
In what follows, many of the generated polynomials have one
‘anonymous’ variable.
This indeterminate is displayed as a question mark (\spadSyntax{?}).

\xtc{
To fix ideas, let's use the field with five elements for the first
few examples.
}{
\spadpaste{GF5 := PF 5; \bound{GF5}}
}
%
%
\xtc{
You can generate irreducible polynomials of any (positive) degree
(within the storage capabilities of the computer and your ability
to wait) by using
\axiomFunFrom{createIrreduciblePoly}{FiniteFieldPolynomialPackage}.
}{
\spadpaste{f := createIrreduciblePoly(8)\$FFPOLY(GF5) \bound{f}\free{GF5}}
}
%
\xtc{
Does this polynomial have other important properties? Use
\axiomFun{primitive?} to test whether it is a primitive polynomial.

```

```

}{
\spadpaste{primitive?(f)\$FFPOLY(GF5) \free{f}}
}
\xtc{
Use \axiomFun{normal?} to test whether it is a normal polynomial.
}{
\spadpaste{normal?(f)\$FFPOLY(GF5) \free{f}}
}
\noindent
Note that this is actually a trivial case,
because a normal polynomial of degree \smath{n}
must have a nonzero term of degree \smath{n-1}.
We will refer back to this later.

\xtc{
To get a primitive polynomial of degree 8 just issue this.
}{
\spadpaste{p := createPrimitivePoly(8)\$FFPOLY(GF5) \bound{p}\free{GF5}}
}
\xtc{
}{
\spadpaste{primitive?(p)\$FFPOLY(GF5) \free{p}}
}
\xtc{
This polynomial is not normal,
}{
\spadpaste{normal?(p)\$FFPOLY(GF5) \free{p}}
}
\xtc{
but if you want a normal one simply write this.
}{
\spadpaste{n := createNormalPoly(8)\$FFPOLY(GF5) \bound{n} \free{GF5}}
}
\xtc{
This polynomial is not primitive!
}{
\spadpaste{primitive?(n)\$FFPOLY(GF5) \free{n}}
}
This could have been seen directly, as
the constant term is 1 here, which is not a primitive
element up to the factor (\axiom{-1}) raised to the degree of the
polynomial.\footnote{Cf. Lidl, R. \& Niederreiter,
H., {\it Finite Fields,} Encycl. of Math. 20, (Addison-Wesley, 1983),
p.90, Th. 3.18.}

```

What about

```

polynomials that are both primitive and normal?
The existence of such a polynomial is by no means obvious.
\footnote{The existence of such polynomials is proved in
Lenstra, H. W. \& Schoof, R. J., {\it Primitive
Normal Bases for Finite Fields,} Math. Comp. 48, 1987, pp. 217-231.}
%
\xtc{
If you really need one use either
\axiomFunFrom{createPrimitiveNormalPoly}{FiniteFieldPolynomialPackage} or
\axiomFunFrom{createNormalPrimitivePoly}{FiniteFieldPolynomialPackage}.
}{
\spadpaste{createPrimitiveNormalPoly(8)\$FFPOLY(GF5) \free{GF5}}
}
%
```

If you want to obtain additional polynomials of the various types above as given by the {\bf create...} operations above, you can use the {\bf next...} operations.

For instance,

```

\axiomFunFrom{nextIrreduciblePoly}{FiniteFieldPolynomialPackage} yields
the next monic irreducible polynomial with the same degree as the input
polynomial.
```

By ‘‘next’’ we mean ‘‘next in a natural order using the terms and coefficients.’’

This will become more clear in the following examples.

```

\xtc{
This is the field with five elements.
}{
\spadpaste{GF5 := PF 5; \bound{GF5}}
}
%
\xtc{
Our first example irreducible polynomial, say
of degree 3, must be ‘‘greater’’ than this.
}{
\spadpaste{h := monomial(1,8)\$SUP(GF5) \bound{h}\free{GF5}}
}
\xtc{
You can generate it by doing this.
}{
\spadpaste{nh := nextIrreduciblePoly(h)\$FFPOLY(GF5) \bound{nh}\free{h}}
}
%
\xtc{
Notice that this polynomial is not the same as the one
```

```

\axiomFunFrom{createIrreduciblePoly}{FiniteFieldPolynomialPackage}.
}{
\spadpaste{createIrreduciblePoly(3)\$FFPOLY(GF5) \free{GF5}}
}
\xtc{
You can step through all irreducible polynomials of degree 8 over
the field with 5 elements by repeatedly issuing this.
}{
\spadpaste{nh := nextIrreduciblePoly(nh)\$FFPOLY(GF5) \free{nh}}
}
\xtc{
You could also ask for the total number of these.
}{
\spadpaste{numberOfIrreduciblePoly(5)\$FFPOLY(GF5) \free{GF5}}
}

```

We hope that ‘‘natural order’’ on polynomials is now clear:
 first we compare the number of monomials of
 two polynomials (‘‘more’’ is ‘‘greater’’);
 then, if necessary, the degrees of these monomials (lexicographically),
 and lastly their coefficients (also
 lexicographically, and using the operation `\axiomFun{lookup}` if
 our field is not a prime field).
 Also note that we make both polynomials monic before looking at the
 coefficients:
 multiplying either polynomial by a nonzero constant
 produces the same result.

```

%
\xtc{
The package
\axiomType{FiniteFieldPolynomialPackage} also provides similar
operations for primitive and normal polynomials. With
the exception of the number of primitive normal polynomials;
we’re not aware of any known formula for this.
}{
\spadpaste{numberOfPrimitivePoly(3)\$FFPOLY(GF5) \free{GF5}}
}
%
%
\xtc{
Take these,
}{
\spadpaste{m := monomial(1,1)\$SUP(GF5) \bound{m}\free{GF5}}
}
\xtc{

```

```

}{
\spadpaste{f := m**3 + 4*m**2 + m + 2 \bound{fx}\free{m}}
}
%
%
\xtc{
and then we have:
}{
\spadpaste{f1 := nextPrimitivePoly(f)\$FFPOLY(GF5) \free{fx}\bound{f1}}
}
\xtc{
What happened?
}{
\spadpaste{nextPrimitivePoly(f1)\$FFPOLY(GF5) \free{f1}}
}
%
Well, for the ordering used in
\axiomFunFrom{nextPrimitivePoly}{FiniteFieldPolynomialPackage} we
use as first criterion a comparison of the constant terms of the
polynomials.
Analogously, in
\axiomFunFrom{nextNormalPoly}{FiniteFieldPolynomialPackage} we first
compare the monomials of degree 1 less than the degree of the
polynomials (which is nonzero, by an earlier remark).
%
\xtc{
}{
\spadpaste{f := m**3 + m**2 + 4*m + 1 \bound{fy} \free{m}}
}
\xtc{
}{
\spadpaste{f1 := nextNormalPoly(f)\$FFPOLY(GF5) \free{fy}\bound{f1y}}
}
\xtc{
}{
\spadpaste{nextNormalPoly(f1)\$FFPOLY(GF5) \free{f1y}}
}
%
\noindent
We don't have to restrict ourselves to prime fields.
%
\xtc{
Let's consider, say, a field with 16 elements.
}{
\spadpaste{GF16 := FFX(FFX(PF 2,2),2); \bound{GF16} }
}

```

```

%
%
\xtc{
We can apply any of the operations described above.
}{
\spadpaste{createIrreduciblePoly(5)\$FFPOLY(GF16) \free{GF16}}
}

\xtc{
Axiom also provides operations
for producing random polynomials of a given degree
}{
\spadpaste{random(5)\$FFPOLY(GF16) \free{GF16}}
}
\xtc{
or with degree between two given bounds.
}{
\spadpaste{random(3,9)\$FFPOLY(GF16) \free{GF16}}
}

\axiomType{\axiom{FiniteFieldPolynomialPackage2}} (abbreviation
\axiomType{FFPOLY2})
exports an operation \axiomFun{rootOfIrreduciblePoly}
for finding one root of an irreducible polynomial \axiom{f}
in an extension field of the coefficient field.
The degree of the extension has to be a multiple of the degree of \axiom{f}.
It is not checked whether \axiom{f} actually is irreducible.

%
\xtc{
To illustrate this operation, we fix a ground field \axiom{GF}
}{
\spadpaste{GF2 := PrimeField 2; \bound{GF2}}
}
%
%
\xtc{
and then an extension field.
}{
\spadpaste{F := FFX(GF2,12) \bound{F}\free{GF2}}
}
%
%
\xtc{
We construct an irreducible polynomial over \axiom{GF2}.
}{

```

```

\spadpaste{f := createIrreduciblePoly(6)\$FFPOLY(GF2)
\bound{fz}\free{GF2}}
}
%
%
\xtc{
We compute a root of \axiom{f}.
}{
\spadpaste{root := rootOfIrreduciblePoly(f)\$FFPOLY2(F,GF2)
\free{F GF2 fz}\bound{root}}
}
%
%and check the result
%\spadcommand{eval(f, monomial(1,1)\$SUP(F) = root) \free{fz F root}}

12.0.185 Primary Decomposition of Ideals

```

<ug08.ht>+≡
\begin{page}{ugProblemIdealPage}{8.12. Primary Decomposition of Ideals}
\beginscroll

```

Axiom provides a facility for the primary decomposition of polynomial ideals over fields of characteristic zero. The algorithm and works in essentially two steps:

```

\indent{4}
\beginitems
\item[1. ] the problem is solved for 0-dimensional ideals by ‘‘generic’’
projection on the last coordinate
\item[2. ] a ‘‘reduction process’’
uses localization and ideal quotients to reduce the general case to
the 0-dimensional one.
\enditems
\indent{0}

```

The Axiom constructor `\axiomType{PolynomialIdeals}` represents ideals with coefficients in any field and supports the basic ideal operations, including intersection, sum and quotient. `\axiomType{IdealDecompositionPackage}` contains the specific operations for the primary decomposition and the computation of the radical of an ideal with polynomial coefficients in a field of characteristic 0 with an effective algorithm for factoring polynomials.

The following examples illustrate the capabilities of this facility.

```

%
\xtc{
First consider the ideal generated by
\texht{$x^2 + y^2 - 1$}\axiom{x**2 + y**2 - 1}
(which defines a circle in the \axiom{(x,y)}-plane) and the ideal
generated by \texht{$x^2 - y^2$}\axiom{x**2 - y**2} (corresponding to the
straight lines \axiom{x = y} and \axiom{x = -y}).
}{
\spadpaste{(n,m) : List DMP([x,y],FRAC INT) \bound{nm}}
}
\xtc{
}{
\spadpaste{m := [x**2+y**2-1] \free{nm} \bound{m}}
}
\xtc{
}{

```

```

\spadpaste{n := [x**2-y**2] \free{nm} \bound{n}}
}
%
%
\xtc{
We find the equations defining the intersection of the two loci.
This correspond to the sum of the associated ideals.
}{
\spadpaste{id := ideal m + ideal n \free{n m} \bound{id}}
}
%
%
\xtc{
We can check if the locus contains only a finite number of points,
that is, if the ideal is zero-dimensional.
}{
\spadpaste{zeroDim? id \free{id}}
}
\xtc{
}{
\spadpaste{zeroDim?(ideal m) \free{m}}
}
\xtc{
}{
\spadpaste{dimension ideal m \free{m}}
}
\xtc{
We can find polynomial relations among the generators
(\axiom{f} and \axiom{g} are the parametric equations of the knot).
}{
\spadpaste{(f,g):DMP([x,y],FRAC INT) \bound{fg}}
}
\xtc{
}{
\spadpaste{f := x**2-1 \free{fg} \bound{f}}
}
\xtc{
}{
\spadpaste{g := x*(x**2-1) \free{fg} \bound{g}}
}
\xtc{
}{
\spadpaste{relationsIdeal [f,g] \free{f g}}
}
\xtc{

```

We can compute the primary decomposition of an ideal.

```
{
\spadpaste{l: List DMP([x,y,z],FRAC INT) \bound{11}}
}
\xtc{
}{
\spadpaste{l:=[x**2+2*y**2,x*z**2-y*z,z**2-4] \free{11} \bound{1}}
}
\xtc{
}{
\spadpaste{ld:=primaryDecomp ideal l \free{1} \bound{ld}}
}
\xtc{
We can intersect back.
}{
\spadpaste{reduce(intersect,ld) \free{ld}}
}
```

```
\xtc{
We can compute the radical of every primary component.
}{
\spadpaste{reduce(intersect,[radical ld.i for i in 1..2]) \free{ld}}
}
\xtc{
Their intersection is equal to the radical of the ideal of \axiom{1}.
}{
\spadpaste{radical ideal l \free{1}}
}
```

12.0.186 Computation of Galois Groups

HyperDoc

Exit Help 8.13. Computation of Galois Groups Home

As a sample use of Axiom's algebraic number facilities, we compute the Galois group of the polynomial $p(x) = x^5 - 5x + 12$.

p := x5 - 5*x + 12**

We would like to construct a polynomial $f(x)$ such that the splitting field of $p(x)$ is generated by one root of $f(x)$. First we construct a polynomial $r = r(x)$ such that one root of $r(x)$ generates the field generated by two roots of the polynomial $p(x)$. (As it will turn out, the field generated by two roots of $p(x)$ is, in fact, the splitting field of $p(x)$.)

From the proof of the primitive element theorem we know that if a and b are algebraic numbers, then the field $\mathbb{Q}(a, b)$ is equal to $\mathbb{Q}(a + k \cdot b)$ for an appropriately chosen integer k . In our case, we construct the minimal polynomial of $a[i] - a[j]$, where $a[i]$ and $a[j]$ are two roots of $p(x)$. We construct this polynomial using **resultant**. The main result we need is the following: If $f(x)$ is a polynomial with roots $a[1] \dots a[m]$ and $g(x)$ is a polynomial with roots $b[1] \dots b[n]$, then the polynomial $h(x) = \text{resultant}(f(y), g(x-y), y)$ is a polynomial of degree $m \cdot n$ with roots $a[i] + b[j]$, $1 \leq i \leq m$, $1 \leq j \leq n$.

For $f(x)$ we use the polynomial $p(x)$. For $g(x)$ we use the

%
\xtc{
}{
\spadpaste{p := x**5 - 5*x + 12 \bound{p}}
}
%
We would like to construct a polynomial \smath{f(x)}
such that the splitting
field
of \smath{p(x)} is generated by one root of \smath{f(x)}.
```

First we construct a polynomial $r = r(x)$ such that one root of $r(x)$ generates the field generated by two roots of the polynomial $p(x)$.

(As it will turn out, the field generated by two roots of $p(x)$ is, in fact, the splitting field of $p(x)$.)

From the proof of the primitive element theorem we know that if a and b are algebraic numbers, then the field $\mathbb{Q}(a,b)$ is equal to $\mathbb{Q}(a + kb)$ for an appropriately chosen integer k .

In our case, we construct the minimal polynomial of $a_i - a_j$, where

a_i and

a_j are two roots of $p(x)$.

We construct this polynomial using `resultant`.

The main result we need is the following:

If $f(x)$ is a polynomial with roots

$a_1 \dots a_m$ and

$g(x)$ is a polynomial

with roots

$b_1 \dots b_n$, then the polynomial

$h(x) = \text{resultant}(f(y), g(x-y), y)$

is a polynomial of degree $m \cdot n$ with

roots

$a_i + b_j$, $i = 1 \dots m$, $j = 1 \dots n$

$\{a_i + b_j, 1 \leq i \leq m, 1 \leq j \leq n\}$.

`\xctc{`

For $f(x)$ we use the polynomial $p(x)$.

For $g(x)$ we use the polynomial $-p(-x)$.

Thus, the polynomial we first construct is

`resultant(p(y), -p(y-x), y)`.

`{`

`\spadpaste{q := resultant(eval(p,x,y),-eval(p,x,y-x),y) \free{p} \bound{q}}`

`}`

`%`

The roots of $q(x)$ are

$a_i - a_j$, $i \leq 1$, $j \leq 5$

$\{a_i - a_j, 1 \leq i, j \leq 5\}$.

Of course, there are five pairs (i,j) with $i = j$,

so 0 is a 5-fold root of $q(x)$.

`%`

`\xctc{`

Let's get rid of this factor.

```
{
\spadpaste{q1 := exquo(q, x**5) \free{q} \bound{q1}}
}
\xtc{
Factor the polynomial \axiom{q1}.
}{
\spadpaste{factoredQ := factor q1 \free{q1} \bound{factoredQ}}
}
```

We see that $\text{\axiom{q1}}$ has two irreducible factors, each of degree $\text{\axiom{10}}$. (The fact that the polynomial $\text{\axiom{q1}}$ has two factors of degree $\text{\axiom{10}}$ is enough to show that the Galois group of $\text{\smath{p(x)}}$ is the dihedral group of order $\text{\axiom{10}}$.)^{\footnote{See McKay, Soicher, Computing Galois Groups over the Rationals, Journal of Number Theory 20, 273-281 (1983). We do not assume the results of this paper, however, and we continue with the computation.}} Note that the type of $\text{\axiom{factoredQ}}$ is $\text{\axiomType{FR POLY INT}}$, that is, $\text{\axiomType{Factored Polynomial Integer}}$. This is a special data type for recording factorizations of polynomials with integer coefficients (see [\downlink{'Factored'}{FactoredXmpPage}](#) $\text{\ignore{Factored}}$).

```
\xtc{
We can access the individual factors using the operation
\axiomFunFrom{nthFactor}{Factored}.
}{
\spadpaste{r := nthFactor(factoredQ,1) \free{factoredQ} \bound{r}}
}
%
```

Consider the polynomial $\text{\smath{r = r(x)}}$.

This is the minimal polynomial of the difference of two roots of $\text{\smath{p(x)}}$.

Thus, the splitting field of $\text{\smath{p(x)}}$ contains a subfield of degree $\text{\axiom{10}}$.

We show that this subfield is, in fact, the splitting field of $\text{\smath{p(x)}}$ by showing that $\text{\smath{p(x)}}$ factors completely over this field.

```
%
\xtc{
First we create a symbolic root of the polynomial \smath{r(x)}.
(We replaced \axiom{x} by \axiom{b} in the
polynomial \axiom{r} so that our symbolic root would be
printed as \axiom{b}.)
}{
\spadpaste{beta:AN := rootOf(eval(r,x,b)) \free{r} \bound{beta}}
```

```

}
\xtc{
We next tell Axiom to view \smath{p(x)} as a univariate polynomial
in \axiom{x}
with algebraic number coefficients.
This is accomplished with this type declaration.
}{
\spadpaste{p := p::UP(x,INT)::UP(x,AN) \free{p} \bound{declareP}}
}
%
%
\xtc{
Factor \smath{p(x)} over the field
\texht{${\bf Q}(\beta)}{\axiom{Q(beta)}}.
(This computation will take some time!)
}{
\spadpaste{algFactors := factor(p,[beta]) \free{declareP beta}
\bound{algFactors}}
}
%
When factoring over number fields, it is important to specify the
field over which the polynomial is to be factored, as polynomials
have different factorizations over different fields.
When you use the operation \axiomFun{factor}, the field over which
the polynomial is factored is the field generated by
\indent{4}
\beginitems
\item[1. ] the algebraic numbers that appear
in the coefficients of the polynomial, and
\item[2. ] the algebraic numbers that
appear in a list passed as an optional second argument of the operation.
\enditems
\indent{0}
In our case, the coefficients of \axiom{p}
are all rational integers and only \axiom{beta}
appears in the list, so the field is simply
\texht{${\bf Q}(\beta)}{\axiom{Q(beta)}}.
%
\xtc{
It was necessary to give the list \axiom{[beta]}
as a second argument of the operation
because otherwise the polynomial would have been factored over the field
generated by its coefficients, namely the rational numbers.
}{
\spadpaste{factor(p) \free{declareP}}
}

```

```
%
We have shown that the splitting field of  $p(x)$  has degree
\axiom{10}.
Since the symmetric group of degree 5 has only one transitive subgroup
of order \axiom{10}, we know that the Galois group of  $p(x)$  must be
this group, the dihedral group
of order \axiom{10}.
Rather than stop here, we explicitly compute the action of the Galois
group on the roots of  $p(x)$ .
```

```
First we assign the roots of  $p(x)$  as the values of five
variables.
```

```
\xctc{
We obtain an individual root by negating the constant coefficient of
one of the factors of  $p(x)$ .
}{
\spadpaste{factor1 := nthFactor(algFactors,1) \free{algFactors}
\bound{factor1}}
}
\xctc{
}{
\spadpaste{root1 := -coefficient(factor1,0) \free{factor1} \bound{root1}}
}
%
%
\xctc{
We obtain a list of all the roots in this way.
}{
\spadpaste{
roots := [-coefficient(nthFactor(algFactors,i),0) for i in 1..5]
\free{algFactors} \bound{roots}}
}
```

```
The expression
```

```
\begin{verbatim}
- coefficient(nthFactor(algFactors, i), 0)}
\end{verbatim}
```

```
is the  $\text{\eth{\axiom{i}}}$  root
of  $p(x)$  and the elements of \axiom{roots} are the  $\text{\eth{\axiom{i}}}$ 
roots of  $p(x)$  as \axiom{i} ranges from \axiom{1} to \axiom{5}.
```

```
\xctc{
Assign the roots as the values of the variables \axiom{a1,...,a5}.
}{
\spadpaste{
(a1,a2,a3,a4,a5) := (roots.1,roots.2,roots.3,roots.4,roots.5)
```

```

\free{roots} \bound{ais}}
}
%
```

Next we express the roots of $\text{\smath{r(x)}}$ as polynomials in $\text{\axiom{beta}}$. We could obtain these roots by calling the operation $\text{\axiomFun{factor}}: \text{\axiom{factor}(r, [beta])}$ factors $\text{\axiom{r(x)}}$ over $\text{\texht{\${\bf Q}(\beta)\$}}\{\text{\axiom{Q(beta)}}\}$. However, this is a lengthy computation and we can obtain the roots of $\text{\smath{r(x)}}$ as differences of the roots $\text{\axiom{a1}, \dots, a5}$ of $\text{\smath{p(x)}}$. Only ten of these differences are roots of $\text{\smath{r(x)}}$ and the other ten are roots of the other irreducible factor of $\text{\axiom{q1}}$. We can determine if a given value is a root of $\text{\smath{r(x)}}$ by evaluating $\text{\smath{r(x)}}$ at that particular value. (Of course, the order in which factors are returned by the operation $\text{\axiomFun{factor}}$ is unimportant and may change with different implementations of the operation. Therefore, we cannot predict in advance which differences are roots of $\text{\smath{r(x)}}$ and which are not.)

```

\xtc{
Let's look at four examples (two are roots of \smath{r(x)} and
two are not).
}{
\spadpaste{eval(r,x,a1 - a2) \free{ais}}
}
\xtc{
}{
\spadpaste{eval(r,x,a1 - a3) \free{ais}}
}
\xtc{
}{
\spadpaste{eval(r,x,a1 - a4) \free{ais}}
}
\xtc{
}{
\spadpaste{eval(r,x,a1 - a5) \free{ais}}
}
%

```

Take one of the differences that was a root of $\text{\smath{r(x)}}$ and assign it to the variable $\text{\axiom{bb}}$.

```

\xtc{
For example, if \axiom{eval(r,x,a1 - a4)} returned \axiom{0}, you would
enter this.
}{
\spadpaste{bb := a1 - a4 \free{ais} \bound{bb}}

```

}
 Of course, if the difference is, in fact, equal to the root $\text{\axiom{beta}}$,
 you should choose another root of $\text{\smath{r(x)}}$.

Automorphisms of the splitting field are given by mapping a generator of
 the field, namely $\text{\axiom{beta}}$, to other roots of its minimal polynomial.
 Let's see what happens when $\text{\axiom{beta}}$ is mapped to $\text{\axiom{bb}}$.

```
%
\xtc{
We compute the images of the roots \axiom{a1,...,a5}
under this automorphism:
}{
\spadpaste{aa1 := subst(a1,beta = bb) \free{beta bb ais} \bound{aa1}}
}
\xtc{
}{
\spadpaste{aa2 := subst(a2,beta = bb) \free{beta bb ais} \bound{aa2}}
}
\xtc{
}{
\spadpaste{aa3 := subst(a3,beta = bb) \free{beta bb ais} \bound{aa3}}
}
\xtc{
}{
\spadpaste{aa4 := subst(a4,beta = bb) \free{beta bb ais} \bound{aa4}}
}
\xtc{
}{
\spadpaste{aa5 := subst(a5,beta = bb) \free{beta bb ais} \bound{aa5}}
}
%
Of course, the values \axiom{aa1,...,aa5} are simply a permutation
of the values \axiom{a1,...,a5}.
%
\xtc{
Let's find the value of \axiom{aa1} (execute as many of the
following five commands as necessary).
}{
\spadpaste{(aa1 = a1) :: Boolean \free{aa1}}
}
\xtc{
}{
\spadpaste{(aa1 = a2) :: Boolean \free{aa1}}
}
\xtc{
}{
```

```

\spadpaste{(aa1 = a3) :: Boolean \free{aa1}}
}
\xtc{
}{
\spadpaste{(aa1 = a4) :: Boolean \free{aa1}}
}
\xtc{
}{
\spadpaste{(aa1 = a5) :: Boolean \free{aa1}}
}

```

Proceeding in this fashion, you can find the values of `\axiom{aa2,...aa5}`. `\footnote{Here you should use the \Cleff{} line editor. See \downlink{''Cleff''}{ugAvailCLEFFPage} in Section 1.1.1\ignore{ugAvailCLEFF} for more information about \Cleff{}.` You have represented the automorphism `\axiom{beta -> bb}` as a permutation of the roots `\axiom{a1,...,a5}`. If you wish, you can repeat this computation for all the roots of `\smath{r(x)}` and represent the Galois group of `\smath{p(x)}` as a subgroup of the symmetric group on five letters.

Here are two other problems that you may attack in a similar fashion:

```

\indent{4}
\beginitems
\item[1. ] Show that the Galois group of
\texht{$p(x) = x^4 + 2 x^3 - 2 x^2 - 3 x + 1$}{\axiom{
p(x) = x**4 + 2*x**3 - 2*x**2 - 3*x + 1}}
is the dihedral group of order eight.
(The splitting field of this polynomial is the Hilbert class field
of
the quadratic field
\texht{$\{\bf Q\}(\sqrt{145})$}{\axiom{Q(sqrt(145))}}.)
\item[2. ] Show that the Galois group of
\texht{$p(x) = x^6 + 108$}{\axiom{p(x) = x**6 + 108}}
has order 6 and is
isomorphic to \texht{$S_3$}{\axiom{S_3}} the symmetric group on three letters.
(The splitting field of this polynomial is the splitting field of
\texht{$x^3 - 2$}{\axiom{x**3 - 2}}.)

12.0.187 Non-Associative Algebras and Genetic Laws

⇒ “notitle” (OctonionXmpPage) 3.81.1 on page 1161

`<ug08.ht>+≡`

```
\begin{page}{ugProblemGeneticPage}
{8.14. Non-Associative Algebras and Genetic Laws}
\beginscroll
```

Many algebraic structures of mathematics and Axiom have a multiplication operation `\axiomOp{*}` that satisfies the associativity law

$$\text{\texht}\{a*(b*c) = (a*b)*c\}\{\spad{a*(b*c) = (a*b)*c}\}$$

for all `\smath{a}`, `\smath{b}` and `\smath{c}`. The octonions (see `\downlink{'Octonion'}{OctonionXmpPage}\ignore{Octonion}`) are a well known exception. There are many other interesting non-associative structures, such as the class of Lie algebras.^{\footnote{Two Axiom implementations of Lie algebras are `\spadtype{LieSquareMatrix}` and `\spadtype{FreeNilpotentLie}`.}} Lie algebras can be used, for example, to analyse Lie symmetry algebras of partial differential equations. In this section we show a different application of non-associative algebras, the modelling of genetic laws.

The Axiom library contains several constructors for creating non-associative structures, ranging from the categories `\spadtype{Monad}`, `\spadtype{NonAssociativeRng}`, and `\spadtype{FramedNonAssociativeAlgebra}`, to the domains `\spadtype{AlgebraGivenByStructuralConstants}` and `\spadtype{GenericNonAssociativeAlgebra}`. Furthermore, the package `\spadtype{AlgebraPackage}` provides operations for analysing the structure of such algebras.^{\footnote{%The interested reader can learn more about these aspects of the Axiom library from the paper ‘‘Computations in Algebras of Finite Rank,’’ by Johannes Grabmeier and Robert Wisbauer, Technical Report, IBM Heidelberg Scientific Center, 1992.}}

Mendel’s genetic laws are often written in a form like

$$\text{\texht}\{\text{\narrowDisplay}\{Aa \times Aa = \{1\over 4\}AA + \{1\over 2\}Aa + \{1\over 4\}aa.\}\}$$

```
{\spad{Aa * Aa = (1/4)*AA + (1/2)*Aa + (1/4)*aa.}
}
```

The implementation of general algebras in Axiom allows us to use this as the definition for multiplication in an algebra. Hence, it is possible to study questions of genetic inheritance using Axiom.

To demonstrate this more precisely, we discuss one example from a monograph of $\text{\texttt{A. W\"{o}rz-Busekros}}$ {A. Woerz-Busekros}, where you can also find a general setting of this theory. ^{\footnote{\text{\texttt{W\"{o}rz-Busekros}}} {Woerz-Busekros}, A., *Algebras in Genetics*, Springer Lectures Notes in Biomathematics 36, Berlin e.a. (1980). In particular, see example 1.3.}

We assume that there is an infinitely large random mating population. Random mating of two gametes $\text{\texttt{\$a_i\$}}$ $\text{\spad{ai}}$ and $\text{\texttt{\$a_j\$}}$ $\text{\spad{aj}}$ gives zygotes $\text{\texttt{\$a_ia_j\$}}$ $\text{\spad{ai aj}}$, which produce new gametes. In classical Mendelian segregation we have $\text{\texttt{\$a_ia_j = {1 \over 2}a_i + {1 \over 2}a_j\$}}$ $\text{\spad{ai aj = (1/2)*ai + (1/2)*aj}}$.

In general, we have $\text{\texttt{\narrowDisplay{a_ia_j = \sum_{k=1}^n \gamma_{i,j}^k a_k}}}$ $\text{\spad{ai aj = gammai1 a1 + gammai2 a2 + ... + gammaijn an}}$. The segregation rates $\text{\texttt{\$ \gamma_{i,j} \$}}$ $\text{\spad{gammai j}}$ are the structural constants of an $\text{\smath{n}}$ -dimensional algebra. This is provided in Axiom by the constructor $\text{\spadtype{AlgebraGivenByStructuralConstants}}$ (abbreviation $\text{\spadtype{ALGSC}}$).

Consider two coupled autosomal loci with alleles $\text{\smath{A}}$, $\text{\smath{a}}$, $\text{\smath{B}}$, and $\text{\smath{b}}$, building four different gametes $\text{\texttt{\$a_1 = AB, a_2 = Ab, a_3 = aB, \$ and \$a_4 = ab\$}}$ $\text{\spad{a1 := AB, a2 := Ab, a3 := aB,} and \spad{a4 := ab}}$. The zygotes $\text{\texttt{\$a_ia_j\$}}$ $\text{\spad{ai aj}}$ produce gametes $\text{\texttt{\$a_i\$}}$ $\text{\spad{ai}}$ and $\text{\texttt{\$a_j\$}}$ $\text{\spad{aj}}$ with classical Mendelian segregation. Zygote $\text{\texttt{\$a_1a_4\$}}$ $\text{\spad{a1 a4}}$ undergoes transition to $\text{\texttt{\$a_2a_3\$}}$ $\text{\spad{a2 a3}}$ and vice versa with probability $\text{\texttt{\$0 \le \theta \le {1 \over 2} \$}}$ $\text{\spad{0 <= theta <= 1/2}}$.

```
\xctc{
```

```

Define a list
\texht{ $[(\gamma_{i,j})^k \mid 1 \leq k \leq 4]$ }\spad{[(gammaij)k 1 <= k <= 4]}
of four four-by-four matrices giving the segregation
rates.
We use the value \smath{1/10} for \smath{\theta}.
}{
\spadpaste{segregationRates : List SquareMatrix(4,FRAC INT) :=
[matrix [ [1, 1/2, 1/2, 9/20], [1/2, 0, 1/20, 0], [1/2, 1/20, 0, 0],
[9/20, 0, 0, 0] ], matrix [ [0, 1/2, 0, 1/20], [1/2, 1, 9/20, 1/2],
[0, 9/20, 0, 0], [1/20, 1/2, 0, 0] ], matrix [ [0, 0, 1/2, 1/20],
[0, 0, 9/20, 0], [1/2, 9/20, 1, 1/2], [1/20, 0, 1/2, 0] ],
matrix [ [0, 0, 0, 9/20], [0, 0, 1/20, 1/2], [0, 1/20, 0, 1/2],
[9/20, 1/2, 1/2, 1] ] ] \bound{segregationRates}}
}
\xtc{
Choose the appropriate symbols for the basis of gametes,
}{
\spadpaste{gametes := ['AB','Ab','aB','ab'] \bound{gametes}}
}
\xtc{
Define the algebra.
}{
\spadpaste{A := ALGSC(FRAC INT, 4, gametes, segregationRates);
\bound{A}\free{gametes, segregationRates}}
}

\xtc{
What are the probabilities for zygote
\texht{ $a_{1a_4}$ }\a1 a4 to produce the different gametes?
}{
\spadpaste{a := basis()\$A; a.1*a.4}
}

Elements in this algebra whose coefficients sum to one play a
distinguished role.
They represent a population with the distribution of gametes
reflected by the coefficients with respect to the basis of
gametes.

Random mating of different populations \smath{x} and \smath{y}
is described by their product \smath{x*y}.

\xtc{
This product is commutative only
if the gametes are not sex-dependent, as in our example.
}{

```

```

\spadpaste{commutative?()\$A \free{A}}
}
\xtc{
In general, it is not associative.
}{
\spadpaste{associative?()\$A \free{A}}
}

```

Random mating within a population $\text{\smath{x}}$ is described by
 $\text{\smath{x*x.}}$
The next generation is $\text{\smath{(x*x)*(x*x).}}$

```

\xtc{
Use decimal numbers to compare the distributions more easily.
}{
\spadpaste{x : ALGSC(DECIMAL, 4, gametes, segregationRates) :=
convert [3/10, 1/5, 1/10, 2/5]\bound{x}\free{gametes, segregationRates}}
}
\xtc{
To compute directly the gametic distribution in the fifth
generation, we use \spadfun{plenaryPower}.
}{
\spadpaste{plenaryPower(x,5) \free{x}}
}

```

We now ask two questions:
Does this distribution converge to an equilibrium state?
What are the distributions that are stable?

```

\xtc{
This is an invariant of the algebra and it is used to answer
the first question.
The new indeterminates describe a symbolic distribution.
}{
\spadpaste{q := leftRankPolynomial()
\GCNAALG(FRAC INT, 4, gametes, segregationRates) ::
UP(Y, POLY FRAC INT)\bound{q}\free{gametes, segregationRates}}
}
\xtc{
Because the coefficient  $\text{\texht{\$9 \over 20}\$}$  $\text{\axiom{9/20}}$  has absolute
value less than 1, all distributions do converge,
by a theorem of this theory.
}{
\spadpaste{factor(q :: POLY FRAC INT) \free{q}}
}
\xtc{

```

The second question is answered by searching for idempotents in the algebra.

```
{
\spadpaste{cI := conditionsForIdempotents()
\GCNAALG(FRAC INT, 4, gametes, segregationRates)
\bound{cI} \free{gametes, segregationRates}}
}
\xtc{
Solve these equations and look at the first solution.
}{
\spadpaste{gbs:= groebnerFactorize cI; gbs.1\free{cI}\bound{gbs}}
}
```

Further analysis using the package `\spadtype{PolynomialIdeals}` shows that there is a two-dimensional variety of equilibrium states and all other solutions are contained in it.

```
\xtc{
Choose one equilibrium state by setting two indeterminates to
concrete values.
}{
\spadpaste{sol := solve concat(gbs.1,[\%x1-1/10,\%x2-1/10])
\bound{sol} \free{gbs}}
}
\xtc{
}{
\spadpaste{e : A := represents reverse (map(rhs, sol.1)
:: List FRAC INT)\bound{e} \free{A, sol}}
}
\xtc{
Verify the result.
}{
\spadpaste{e*e-e \free{e}}
}

Programming in the interpreter is easy.
So is the use of Axiom’s graphics facility.
Both are rather flexible and allow you to use them for many
interesting applications.
However, both require learning some basic ideas and skills.

All graphics examples in the `\Gallery{}` section are either
produced directly by interactive commands or by interpreter
programs.
Four of these programs are introduced here.

By the end of this chapter you will know enough about graphics and programming in the interpreter to not only understand all these examples, but to tackle interesting and difficult problems on your own.

\downlink{‘‘Programs for Axiom Images’’}{ugAppGraphicsPage} in Appendix G\ignore{ugAppGraphics} lists all the remaining commands and programs used to create these images.

```
<ug10.ht>+≡
\begin{page}{ugIntProgDrawingPage}{10.1. Drawing Ribbons Interactively}
\beginscroll
%
```

We begin our discussion of interactive graphics with the creation of a useful facility: plotting ribbons of two-graphs in three-space.

Suppose you want to draw the $\text{\twodim{}}$ graphs of $\text{\smath{n}}$ functions $\text{\texht{\$f_i(x), 1 \leq i \leq n, \$}}\{\text{\spad{f_i(x), 1 \leq i \leq 5,}}\}$ all over some fixed range of $\text{\smath{x}}$.

One approach is to create a $\text{\twodim{}}$ graph for each one, then superpose one on top of the other.

What you will more than likely get is a jumbled mess.

Even if you make each function a different color, the result is likely to be confusing.

A better approach is to display each of the $\text{\smath{f_i(x)}}$ in three dimensions as a ‘‘ribbon’’ of some appropriate width along the $\text{\smath{y}}$ -direction, laying down each ribbon next to the previous one.

A ribbon is simply a function of $\text{\smath{x}}$ and $\text{\smath{y}}$ depending only on $\text{\smath{x}}$.

We illustrate this for $\text{\smath{f_i(x)}}$ defined as simple powers of $\text{\smath{x}}$ for $\text{\smath{x}}$ ranging between $\text{\smath{-1}}$ and $\text{\smath{1}}$.

```
\psXtc{
Draw the ribbon for \texht{\$z = x^2\$}\{\spad{z=x ** 2}\}.
}{
\graphpaste{draw(x**2,x=-1..1,y=0..1)}
}{
\epsffile[0 0 295 295]{../ps/ribbon1.ps}
}
```

Now that was easy!

What you get is a ‘‘wire-mesh’’ rendition of the ribbon.

That’s fine for now.

Notice that the mesh-size is small in both the $\text{\smath{x}}$ and the $\text{\smath{y}}$ directions.

Axiom normally computes points in both these directions.

This is unnecessary.

One step is all we need in the $\backslash\mathrm{smath}\{y\}$ -direction.

To have Axiom economize on $\backslash\mathrm{spad}\{y\}$ -points, we re-draw the ribbon with option $\backslash\mathrm{spad}\{\mathrm{var2Steps} == 1\}$.

```
\psXtc{
Re-draw the ribbon, but with option \spad{var2Steps == 1}
so that only \spad{1} step is computed in the
\smath{y} direction.
}{
\graphpaste{vp := draw(x**2,x=-1..1,y=0..1,var2Steps==1) \bound{d1}}
}{
\epsffile[0 0 295 295]{../ps/ribbon2.ps}
}
```

The operation has created a viewport, that is, a graphics window on your screen.

We assigned the viewport to $\backslash\mathrm{spad}\{vp\}$ and now we manipulate its contents.

Graphs are objects, like numbers and algebraic expressions.

You may want to do some experimenting with graphs.

For example, say

```
\begin{verbatim}
showRegion(vp, "on")
\end{verbatim}
```

to put a bounding box around the ribbon.

Try it!

Issue $\backslash\mathrm{spad}\{\mathrm{rotate}(vp, -45, 90)\}$ to rotate the figure $\backslash\mathrm{smath}\{-45\}$ longitudinal degrees and $\backslash\mathrm{smath}\{90\}$ latitudinal degrees.

```
\psXtc{
Here is a different rotation.
This turns the graph so you can view it along the \smath{y}-axis.
}{
\spadpaste{rotate(vp, 0, -90)\bound{d3}\free{d1}}
}{
\epsffile[0 0 295 295]{../ps/ribbon2r.ps}
}
```

There are many other things you can do.

In fact, most everything you can do interactively using the $\backslash\mathrm{threedim}\{\}$ control panel (such as translating, zooming, resizing, coloring, perspective and lighting selections) can also be done

directly by operations (see [\downlink{‘Graphics’}{ugGraphPage}](#) in Chapter 7\ignore{ugGraph} for more details).

When you are done experimenting, say `\spad{reset(vp)}` to restore the picture to its original position and settings.

Let’s add another ribbon to our picture---one for `\texht{x^3}`\spad{x**3}. Since `\smath{y}` ranges from `\smath{0}` to `\smath{1}` for the first ribbon, now let `\smath{y}` range from `\smath{1}` to `\smath{2}`.

This puts the second ribbon next to the first one.

How do you add a second ribbon to the viewport?

One method is

to extract the ‘space’ component from the viewport using the operation

`\spadfunFrom{subspace}{ThreeDimensionalViewport}`.

You can think of the space component as the object inside the window (here, the ribbon).

Let’s call it `\spad{sp}`.

To add the second ribbon, you draw the second ribbon using the option `\spad{space == sp}`.

```
\xrc{
Extract the space component of \spad{vp}.
}{
\spadpaste{sp := subspace(vp)\bound{d5}\free{d1}}
}

\psXrc{
Add the ribbon for
\texht{$x^3$}\spad{x**3} alongside that for
\texht{$x^2$}\spad{x**2}.
}{
\graphpaste{vp := draw(x**3,x=-1..1,y=1..2,var2Steps==1, space==sp)
\bound{d6}\free{d5}}
}{
\epsffile[0 0 295 295]{../ps/ribbons.ps}
}
```

Unless you moved the original viewport, the new viewport covers the old one.

You might want to check that the old object is still there by moving the top window.

Let's show quadrilateral polygon outlines on the ribbons and then enclose the ribbons in a box.

```
\psXtc{
Show quadrilateral polygon outlines.
}{
\spadpaste{drawStyle(vp,"shade");outlineRender(vp,"on")
\bound{d10}\free{d6}}
}{
\epsffile[0 0 295 295]{../ps/ribbons2.ps}
}
\psXtc{
Enclose the ribbons in a box.
}{
\spadpaste{rotate(vp,20,-60); showRegion(vp,"on")\bound{d11}\free{d10}}
}{
\epsffile[0 0 295 295]{../ps/ribbons2b.ps}
}
```

This process has become tedious!

If we had to add two or three more ribbons, we would have to repeat the above steps several more times.

It is time to write an interpreter program to help us take care of the details.

13.0.190 A Ribbon Program

⇒ “notitle” (ugUserPage) 10.0.95 on page 2043

⇒ “notitle” (ugLangBlocksPage) 9.0.76 on page 1961

(ug10.ht)+≡

```
\begin{page}{ugIntProgRibbonPage}{10.2. A Ribbon Program}
\beginscroll
%
```

The above approach creates a new viewport for each additional ribbon.

A better approach is to build one object composed of all ribbons before creating a viewport.

To do this, use `\spadfun{makeObject}` rather than `\spadfun{draw}`.

The operations have similar formats, but

`\spadfun{draw}` returns a viewport and

`\spadfun{makeObject}` returns a space object.

We now create a function `\userfun{drawRibbons}` of two arguments:

`\spad{flist}`, a list of formulas for the ribbons you want to draw,

and `\spad{xrange}`, the range over which you want them drawn.

Using this function, you can just say

```
\begin{verbatim}
drawRibbons([x**2, x**3], x=-1..1)
\end{verbatim}
```

to do all of the work required in the last section.

Here is the `\userfun{drawRibbons}` program.

Invoke your favorite editor and create a file called `{\bf ribbon.input}` containing the following program.

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ drawRibbons(flist,\ xrange)\ ==}\newline
{\tt 2.\ \ \ \ \ sp\ :=\ createThreeSpace()}\newline
{\tt 3.\ \ \ \ \ y0\ :=\ 0}\newline
{\tt 4.\ \ \ \ \ for\ f\ in\ flist\ repeat}\newline
{\tt 5.\ \ \ \ \ \ \ makeObject(f,\ xrange,\ y=y0..y0+1,\ }\newline
{\tt 6.\ \ \ \ \ \ \ \ \ space==sp,\ var2Steps\ ==\ 1)}\newline
{\tt 7.\ \ \ \ \ \ \ y0\ :=\ y0\ +\ 1}\newline
{\tt 8.\ \ \ \ \ \ vp\ :=\ makeViewport3D(sp,\ "Ribbons")}\newline
{\tt 9.\ \ \ \ \ \ drawStyle(vp,\ "shade")}\newline
{\tt 10.\ \ \ \ \ outlineRender(vp,\ "on")}\newline
{\tt 11.\ \ \ \ \ showRegion(vp,"on")}\newline
```

```

{\tt 12.\ \ \ n :=\ \#\ flist}\newline
{\tt 13.\ \ \ zoom(vp,n,1,n)}\newline
{\tt 14.\ \ \ rotate(vp,0,75)}\newline
{\tt 15.\ \ \ vp}\newline
\caption{The first \protect\pspadfun{drawRibbons} function.}
\label{fig-ribdraw1}
\endImportant

```

Here are some remarks on the syntax used in the `\pspadfun{drawRibbons}` function (consult `\downlink{‘‘User-Defined Functions, Macros and Rules’’}{ugUserPage}` in Chapter 6`\ignore{ugUser}` for more details). Unlike most other programming languages which use semicolons, parentheses, or `{\it begin}--{\it end}` brackets to delineate the structure of programs, the structure of an Axiom program is determined by indentation. The first line of the function definition always begins in column 1. All other lines of the function are indented with respect to the first line and form a `\spadgloss{pile}` (see `\downlink{‘‘Blocks’’}{ugLangBlocksPage}` in Section 5.2`\ignore{ugLangBlocks}`).

The definition of `\userfun{drawRibbons}` consists of a pile of expressions to be executed one after another. Each expression of the pile is indented at the same level. Lines 4-7 designate one single expression: since lines 5-7 are indented with respect to the others, these lines are treated as a continuation of line 4. Also since lines 5 and 7 have the same indentation level, these lines designate a pile within the outer pile.

The last line of a pile usually gives the value returned by the pile. Here it is also the value returned by the function. Axiom knows this is the last line of the function because it is the last line of the file. In other cases, a new expression beginning in column one signals the end of a function.

The line `\spad{drawStyle(vp,"shade")}` is given after the viewport has been created to select the draw style. We have also used the `\spadfunFrom{zoom}{ThreeDimensionalViewport}` option. Without the `zoom`, the viewport region would be scaled equally in all three coordinate directions.

Let's try the function `\userfun{drawRibbons}`. First you must read the file to give Axiom the function definition.

```

\xtc{
Read the input file.

```

```

}{
\spadpaste{read ribbon \bound{s0}}
}

13.0.191 Coloring and Positioning Ribbons

```
<ug10.ht>+≡
\begin{page}{ugIntProgColorPage}{10.3. Coloring and Positioning Ribbons}
\beginscroll
%
```

Before leaving the ribbon example, we make two improvements. Normally, the color given to each point in the space is a function of its height within a bounding box. The points at the bottom of the box are red, those at the top are purple.

To change the normal coloring, you can give an option `\spad{colorFunction == {\it function}}`. When Axiom goes about displaying the data, it determines the range of colors used for all points within the box. Axiom then distributes these numbers uniformly over the number of hues. Here we use the simple color function `\texht{$(x,y) \mapsto i$}{(x,y) +-> i}` for the `\eth{\smath{i}}` ribbon.

Also, we add an argument `\spad{yrange}` so you can give the range of `\spad{y}` occupied by the ribbons. For example, if the `\spad{yrange}` is given as `\spad{y=0..1}` and there are `\smath{5}` ribbons to be displayed, each ribbon would have width `\smath{0.2}` and would appear in the range `\texht{$0 \leq y \leq 1$}{\spad{0 <= y <= 1}}`.

Refer to lines 4-9.

Line 4 assigns to `\spad{yVar}` the variable part of the `\spad{yrange}` (after all, it need not be `\spad{y}`). Suppose that `\spad{yrange}` is given as `\spad{t = a..b}` where `\spad{a}` and `\spad{b}` have numerical values. Then line 5 assigns the value of `\spad{a}` to the variable `\spad{y0}`. Line 6 computes the width of the ribbon by dividing the difference of `\spad{a}` and `\spad{b}` by the number, `\spad{num}`, of ribbons. The result is assigned to the variable `\spad{width}`. Note that in the for-loop in line 7, we are iterating in parallel; it is not a nested loop.

```
\beginImportant

13.0.192 Points, Lines, and Curves

```

<ug10.ht>+≡
\begin{page}{ugIntProgPLCPage}{10.4. Points, Lines, and Curves}
\beginscroll
%
What you have seen so far is a high-level program using the
graphics facility.
We now turn to the more basic notions of points, lines, and curves
in \threedim{} graphs.
These facilities use small floats (objects
of type \spadtype{DoubleFloat}) for data.
Let us first give names to the small float values \smath{0} and
\smath{1}.
\xtc{
The small float 0.
}{
\spadpaste{zero := 0.0@DFLOAT \bound{d1}}
}
\xtc{
The small float 1.
}{
\spadpaste{one := 1.0@DFLOAT \bound{d2}}
}
The \spadSyntax{@} sign means ‘‘of the type.’’ Thus \spad{zero} is
\smath{0.0} of the type \spadtype{DoubleFloat}.
You can also say \spad{0.0::DFLOAT}.

Points can have four small float components: \smath{x, y, z}
coordinates and an optional color. A ‘‘curve’’ is simply a list of
points connected by straight line segments.
\xtc{
Create the point \spad{origin} with color zero, that is, the lowest color
on the color map.
}{
\spadpaste{origin := point [zero,zero,zero,zero] \free{d1}\bound{d3}}
}
\xtc{
Create the point \spad{unit} with color zero.
}{
\spadpaste{unit := point [one,one,one,zero] \free{d1 d2}\bound{d4}}
}
\xtc{
Create the curve (well, here, a line) from
\spad{origin} to \spad{unit}.
}{

```

```
\spadpaste{line := [origin, unit] \free{d3 d4} \bound{d5}}
}
```

We make this line segment into an arrow by adding an arrowhead. The arrowhead extends to, say, `\spad{p3}` on the left, and to, say, `\spad{p4}` on the right. To describe an arrow, you tell Axiom to draw the two curves `\spad{[p1, p2, p3]}` and `\spad{[p2, p4]}`. We also decide through experimentation on values for `\spad{arrowScale}`, the ratio of the size of the arrowhead to the stem of the arrow, and `\spad{arrowAngle}`, the angle between the arrowhead and the arrow.

Invoke your favorite editor and create an input file called `{\bf arrows.input}`. This input file first defines the values of `%\spad{origin}`, `\spad{unit}`, `\spad{arrowAngle}` and `\spad{arrowScale}`, then defines the function `\userfun{makeArrow}\texht{(p_1, p_2)}\{(p1, p2)\}` to draw an arrow from point `\texht{p_1}\{p1\}` to `\texht{p_2}\{p2\}`.

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ \ arrowAngle\ :=\ \%pi-\%pi/10.0@DFLOAT}\newline
{\tt 2.\ \ \ \ arrowScale\ :=\ 0.2@DFLOAT}\newline
{\tt 3.\ \ \ \ }\newline
{\tt 4.\ \ \ \ makeArrow(p1,\ p2)\ ==}\newline
{\tt 5.\ \ \ \ \ \ \ \ \ delta\ :=\ p2\ -\ p1}\newline
{\tt 6.\ \ \ \ \ \ \ \ \ len\ :=\ arrowScale\ *\ length\ delta}\newline
{\tt 7.\ \ \ \ \ \ \ \ \ theta\ :=\ atan(delta.1,\ delta.2)}\newline
{\tt 8.\ \ \ \ \ \ \ \ \ c1\ :=\ len*cos(theta\ +\ arrowAngle)}\newline
{\tt 9.\ \ \ \ \ \ \ \ \ s1\ :=\ len*sin(theta\ +\ arrowAngle)}\newline
{\tt 10.\ \ \ \ \ \ \ \ \ c2\ :=\ len*cos(theta\ -\ arrowAngle)}\newline
{\tt 11.\ \ \ \ \ \ \ \ \ s2\ :=\ len*sin(theta\ -\ arrowAngle)}\newline
{\tt 12.\ \ \ \ \ \ \ \ \ z\ \ :=\ p2.3*(1\ -\ arrowScale)}\newline
{\tt 13.\ \ \ \ \ \ \ \ \ p3\ :=\ point\ [p2.1\ +\ c1,\ p2.2\ +\ s1,\ z,\ p2.4]}\newline
{\tt 14.\ \ \ \ \ \ \ \ \ p4\ :=\ point\ [p2.1\ +\ c2,\ p2.2\ +\ s2,\ z,\ p2.4]}\newline
{\tt 15.\ \ \ \ \ \ \ \ \ [[p1,\ p2,\ p3],\ [p2,\ p4]]}\newline
\endImportant
```

Read the file and then create an arrow from the point `\spad{origin}` to the point `\spad{unit}`.
`\xctc{`

```

Read the input file defining \userfun{makeArrow}.
}{
\spadpaste{read arrows\bound{v1}}
}
\xtc{
Construct the arrow (a list of two curves).
}{
\spadpaste{arrow := makeArrow(origin,unit)\bound{v2}\free{v1 d3 d4}}
}
\xtc{
Create an empty object \spad{sp} of type \spad{ThreeSpace}.
}{
\spadpaste{sp := createThreeSpace()\bound{c1}}
}
\xtc{
Add each curve of the arrow to the space \spad{sp}.
}{
\spadpaste{for a in arrow repeat sp := curve(sp,a)
\bound{v3}\free{v2}\free{c1}}
}
\psXtc{
Create a \threedim{} viewport containing that space.
}{

13.0.193 A Bouquet of Arrows

<ug10.ht>+≡

```
\begin{page}{ugIntProgColorArrPage}{10.5. A Bouquet of Arrows}
\beginscroll
```

Let's draw a "bouquet" of arrows.
 Each arrow is identical. The arrowheads are
 uniformly placed on a circle parallel to the $\text{\smath{xy}}$ -plane.
 Thus the position of each arrow differs only
 by the angle $\text{\texht{\theta}}$,
 $\text{\texht{\$0 \leq \theta < 2\pi}}$,
 between the arrow and
 the $\text{\smath{x}}$ -axis on the $\text{\smath{xy}}$ -plane.

Our bouquet is rather special: each arrow has a different
 color (which won't be evident here, unfortunately).
 This is arranged by letting the color of each successive arrow be
 denoted by $\text{\texht{\theta}}$.
 In this way, the color of arrows ranges from red to green to violet.
 Here is a program to draw a bouquet of $\text{\smath{n}}$ arrows.

```
\beginImportant
```

```

13.0.194 Drawing Complex Vector Fields

```

\ug10.ht)+≡
\begin{page}{ugIntProgVecFieldsPage}{10.6. Drawing Complex Vector Fields}
\beginscroll

```

We now put our arrows to good use drawing complex vector fields. These vector fields give a representation of complex-valued functions of complex variables.

Consider a Cartesian coordinate grid of points (x, y) in the plane, and some complex-valued function f defined on this grid.

At every point on this grid, compute the value of $f(x + iy)$ and call it z .

Since z has both a real and imaginary value for a given (x, y) grid point, there are four dimensions to plot.

What do we do?

We represent the values of z by arrows planted at each grid point.

Each arrow represents the value of z in polar coordinates (r, θ) .

The length of the arrow is proportional to r .

Its direction is given by θ .

The code for drawing vector fields is in the file `\bf vectors.input`. We discuss its contents from top to bottom.

Before showing you the code, we have two small matters to take care of.

First, what if the function has large spikes, say, ones that go off to infinity?

We define a variable `\spad{clipValue}` for this purpose. When `\spad{r}` exceeds the value of `\spad{clipValue}`, then the value of `\spad{clipValue}` is used instead of that for `\spad{r}`.

For convenience, we define a function `\spad{clipFun(x)}` which uses `\spad{clipValue}` to ‘clip’ the value of `\spad{x}`.

```

%
\beginImportant

\noindent
{\tt 1.\ \ \ clipValue\ :=\ DFL0AT\ :=\ 6}\newline
{\tt 2.\ \ \ clipFun(x)\ ==\ min(max(x,-clipValue),clipValue)}\newline
\endImportant

```

Notice that we identify `\spad{clipValue}` as a small float but do

not declare the type of the function `\userfun{clipFun}`.
 As it turns out, `\userfun{clipFun}` is called with a small float value.
 This declaration ensures that `\userfun{clipFun}` never does a conversion when it is called.

The second matter concerns the possible ‘poles’ of a function, the actual points where the spikes have infinite values.

Axiom uses normal `\spadtype{DoubleFloat}` arithmetic which does not directly handle infinite values.
 If your function has poles, you must adjust your step size to avoid landing directly on them (Axiom calls `\spadfun{error}` when asked to divide a value by `\axiom{0}`, for example).

We set the variables `\spad{realSteps}` and `\spad{imagSteps}` to hold the number of steps taken in the real and imaginary directions, respectively.
 Most examples will have ranges centered around the origin.
 To avoid a pole at the origin, the number of points is taken to be odd.

`\beginImportant`

```
\noindent
{\tt 1.\ \ \ realSteps:\ INT\ :=\ 25}\newline
{\tt 2.\ \ \ imagSteps:\ INT\ :=\ 25}\newline
{\tt 3.\ \ \ )read\ arrows}\newline
\endImportant
```

Now define the function `\userfun{drawComplexVectorField}` to draw the arrows. It is good practice to declare the type of the main function in the file. This one declaration is usually sufficient to ensure that other lower-level functions are compiled with the correct types.

`\beginImportant`

```
\noindent
{\tt 4.\ \ \ C\ :=\ Complex\ DoubleFloat}\newline
{\tt 5.\ \ \ S\ :=\ Segment\ DoubleFloat}\newline
{\tt 6.\ \ \ drawComplexVectorField:\ (C\ ->\ C,\ S,\ S)\ ->\ VIEW3D}\newline
\endImportant
```

The first argument is a function mapping complex small floats into complex small floats.

The second and third arguments give the range of real and

imaginary values as segments like `\spad{a..b}`.

The result is a `\threedim{}` viewport.

Here is the full function definition:

13.0.195 Drawing Complex Functions

⇒ “notitle” (ugGraphPage) 11.0.122 on page 2208

ug10.ht+≡

```
\begin{page}{ugIntProgCompFunsPage}{10.7. Drawing Complex Functions}
\beginscroll
```

Here is another way to graph a complex function of complex arguments. For each complex value z , compute $f(z)$, again expressing the value in polar coordinates (r, θ) . We draw the complex valued function, again considering the (x, y) -plane as the complex plane, using r as the height (or z -coordinate) and θ as the color. This is a standard plot---we learned how to do this in [\downlink{‘Graphics’}{ugGraphPage}](#) in Chapter 7~~\ignore{ugGraph}~~---but here we write a new program to illustrate the creation of polygon meshes, or grids.

Call this function `\userfun{drawComplex}`. It displays the points using the “mesh” of points. The function definition is in three parts.

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ drawComplex:\ (C\ ->\ C,\ S,\ S)\ ->\ VIEW3D}\newline
{\tt 2.\ \ \ drawComplex(f,\ realRange,\ imagRange)\ ==}\newline
{\tt 3.\ \ \ \ \ delReal\ :=\ (hi(realRange)-lo(realRange))/realSteps}
\newline
{\tt 4.\ \ \ \ \ delImag\ :=\ (hi(imagRange)-lo(imagRange))/imagSteps}
\newline
{\tt 5.\ \ \ \ \ llp:List\ List\ Point\ DFLOAT\ :=\ []}\newline
\endImportant
```

Variables `\spad{delReal}` and `\spad{delImag}` give the step sizes along the real and imaginary directions as computed by the values of the global variables `\spad{realSteps}` and `\spad{imagSteps}`. The mesh is represented by a list of lists of points `\spad{llp}`, initially empty. Now `\spad{[]}` alone is ambiguous, so to set this initial value you have to tell Axiom what type of empty list it is. Next comes the loop which builds `\spad{llp}`.

```
\beginImportant
```

```

\noindent
{\tt 1.\ \ \ \ \ real\ :=\ lo(realRange)}\newline
{\tt 2.\ \ \ \ \ for\ i\ in\ 1..realSteps+1\ repeat}\newline
{\tt 3.\ \ \ \ \ \ \ \ imag\ :=\ lo(imagRange)}\newline
{\tt 4.\ \ \ \ \ \ \ \ lp\ :=\ []\$(List\ Point\ DFLOAT)}\newline
{\tt 5.\ \ \ \ \ \ \ \ for\ j\ in\ 1..imagSteps+1\ repeat}\newline
{\tt 6.\ \ \ \ \ \ \ \ \ z\ :=\ f\ complex(real,imag)}\newline
{\tt 7.\ \ \ \ \ \ \ \ \ pt\ :=\ point\
[real,imag,\ clipFun\ sqrt\ norm\ z,\ ]}\newline
{\tt 8.\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ argument\ z]}\
\newline
{\tt 9.\ \ \ \ \ \ \ \ \ lp\ :=\ cons(pt,lp)}\newline
{\tt 10.\ \ \ \ \ \ \ \ \ imag\ :=\ imag\ +\ delImag}\newline
{\tt 11.\ \ \ \ \ \ \ \ real\ :=\ real\ +\ delReal}\newline
{\tt 12.\ \ \ \ \ \ \ \ llp\ :=\ cons(lp,\ llp)}\newline
\endImportant

```

The code consists of both an inner and outer loop. Each pass through the inner loop adds one list `\spad{lp}` of points to the list of lists of points `\spad{llp}`. The elements of `\spad{lp}` are collected in reverse order.

```
\beginImportant
```

```

\noindent
{\tt 13.\ \ \ \ \ makeViewport3D(mesh(llp),\ "Complex\ Function")}\newline
\endImportant

```

The operation `\spadfun{mesh}` then creates an object of type `\spadtype{ThreeSpace(DoubleFloat)}` from the list of lists of points. This is then passed to `\spadfun{makeViewport3D}` to display the image.

Now add this function directly to your `{\bf vectors.input}` file and re-read the file using `\spad{}read vectors}`. We try `\userfun{drawComplex}` using a user-defined function `\spad{f}`.

```

\xtc{
Read the file.
}{
\spadpaste{}read vectors \bound{readVI}}
}
\xtc{
This one has a pole at \smath{z=0}.
}{
\spadpaste{f(z) == exp(1/z)\bound{e1}}
}

```

```

}
\psXtc{
Draw it with an odd number of steps to avoid the pole.
}{
\graphpaste{drawComplex(f,-2..2,-2..2)\free{e1 readVI}}
}{
\epsffile[0 0 295 295]{../ps/complexexp.ps}

13.0.196 Functions Producing Functions

⇒ “notitle” (ugUserMakePage) 10.0.112 on page 2120

```
<ug10.ht>+≡
\begin{page}{ugIntProgFunctionsPage}{10.8. Functions Producing Functions}
\beginscroll
```

In \downlink{‘‘Making Functions from Objects’’}{ugUserMakePage} in Section 6.14\ignore{ugUserMake}, you learned how to use the operation `\spadfun{function}` to create a function from symbolic formulas. Here we introduce a similar operation which not only creates functions, but functions from functions.

The facility we need is provided by the package `\spadtype{MakeUnaryCompiledFunction(E,S,T)}`. This package produces a unary (one-argument) compiled function from some symbolic data generated by a previous computation.\footnote{%
`\spadtype{MakeBinaryCompiledFunction}` is available for binary functions.} The `\spad{E}` tells where the symbolic data comes from; the `\spad{S}` and `\spad{T}` give Axiom the source and target type of the function, respectively. The compiled function produced has type `\spadsig{\spad{S}}{\spad{T}}`. To produce a compiled function with definition `\spad{p(x) == expr}`, call `\spad{compiledFunction(expr, x)}` from this package. The function you get has no name. You must to assign the function to the variable `\spad{p}` to give it that name. %
`\xct{ Do some computation. }{ \spadpaste{(x+1/3)**5\bound{p1}} }`
`\xct{ Convert this to an anonymous function of \spad{x}. Assign it to the variable \spad{p} to give the function a name. }{ \spadpaste{p := compiledFunction(\%,x)\$MakeUnaryCompiledFunction(POLY FRAC INT,DFLOAT,DFLOAT)\bound{p2}\free{p1}} }` `\xct{ Apply the function. }{ \spadpaste{p(sin(1.3))\bound{p3}\free{p2}} }`

For a more sophisticated application, read on.

13.0.197 Automatic Newton Iteration Formulas

⇒ “notitle” (MappingPackageOneXmpPage) 3.73.1 on page 1072

`<ug10.ht>+≡`

```
\begin{page}{ugIntProgNewtonPage}
{10.9. Automatic Newton Iteration Formulas}
\beginscroll
```

We resume

our continuing saga of arrows and complex functions.

Suppose we want to investigate the behavior of Newton’s iteration function in the complex plane.

Given a function $\text{\smath{f}}$, we want to find the complex values $\text{\smath{z}}$ such that $\text{\smath{f(z)} = 0}$.

The first step is to produce a Newton iteration formula for a given $\text{\smath{f}}$:

```
\texht{$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$}
\spad{x(n+1) = x(n) - f(x(n))/f'(x(n))}.
```

We represent this formula by a function $\text{\smath{g}}$

that performs the computation on the right-hand side, that is,

```
\texht{$x_{n+1} = g(x_n)$}
\spad{x(n+1) = g(x(n))}.
```

The type `\spadtype{Expression Integer}` (abbreviated `\spadtype{EXPR INT}`) is used to represent general symbolic expressions in Axiom.

To make our facility as general as possible, we assume

$\text{\smath{f}}$ has this type.

Given $\text{\smath{f}}$, we want

to produce a Newton iteration function $\text{\spad{g}}$ which, given a complex point $\text{\texht{$x_n$}}$ $\{x(n)\}$, delivers the next Newton iteration point $\text{\texht{$x_{n+1}$}}$ $\{x(n+1)\}$.

This time we write an input file called `{\bf newton.input}`.

We need to import `\spadtype{MakeUnaryCompiledFunction}` (discussed in the last section), call it with appropriate types, and then define the function `\spad{newtonStep}` which references it.

Here is the function `\spad{newtonStep}`:

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ C\ :=\ Complex\ DoubleFloat}\newline
```

```
{\tt 2.\ \ \ complexFunPack:=MakeUnaryCompiledFunction(EXPR\ INT,C,C)}
```

```

\newline
{\tt 3.\ \ \ }\newline
{\tt 4.\ \ \ newtonStep(f)\ ==}\newline
{\tt 5.\ \ \ \ \ fun\ \ :=\ complexNumericFunction\ f}\newline
{\tt 6.\ \ \ \ \ deriv\ :=\ complexDerivativeFunction(f,1)}\newline
{\tt 7.\ \ \ \ \ (x:C):C\ +->}\newline
{\tt 8.\ \ \ \ \ \ \ x\ -\ fun(x)/deriv(x)}\newline
{\tt 9.\ \ \ }\newline
{\tt 10.\ \ \ complexNumericFunction\ f\ ==}\newline
{\tt 11.\ \ \ \ \ v\ :=\ theVariableIn\ f}\newline
{\tt 12.\ \ \ \ \ compiledFunction(f,\ v)\ $complexFunPack}\newline
{\tt 13.\ \ \ }\newline
{\tt 14.\ \ \ complexDerivativeFunction(f,n)\ ==}\newline
{\tt 15.\ \ \ \ \ v\ :=\ theVariableIn\ f}\newline
{\tt 16.\ \ \ \ \ df\ :=\ D(f,v,n)}\newline
{\tt 17.\ \ \ \ \ compiledFunction(df,\ v)\ $complexFunPack}\newline
{\tt 18.\ \ \ }\newline
{\tt 19.\ \ \ theVariableIn\ f\ ==\ \ \ }\newline
{\tt 20.\ \ \ \ \ vl\ :=\ variables\ f}\newline
{\tt 21.\ \ \ \ \ nv\ :=\ \#\ vl}\newline
{\tt 22.\ \ \ \ \ nv\ >\ 1\ =>\ error\ "Expression\ is\ not\ univariate."}
\newline
{\tt 23.\ \ \ \ \ nv\ =\ 0\ =>\ 'x}\newline
{\tt 24.\ \ \ \ \ first\ vl}\newline
\endImportant

```

Do you see what is going on here?

A formula `\spad{f}` is passed into the function `\userfun{newtonStep}`. First, the function turns `\spad{f}` into a compiled program mapping complex numbers into complex numbers. Next, it does the same thing for the derivative of `\spad{f}`. Finally, it returns a function which computes a single step of Newton's iteration.

The function `\userfun{complexNumericFunction}` extracts the variable from the expression `\spad{f}` and then turns `\spad{f}` into a function which maps complex numbers into complex numbers. The function `\userfun{complexDerivativeFunction}` does the same thing for the derivative of `\spad{f}`. The function `\userfun{theVariableIn}` extracts the variable from the expression `\spad{f}`, calling the function `\spadfun{error}` if `\spad{f}` has more than one variable. It returns the dummy variable `\spad{x}` if `\spad{f}` has no variables.

Let's now apply `\userfun{newtonStep}` to the formula for computing cube roots of two.

```

%
\xtc{

```

```

Read the input file with the definitions.
}{
\spadpaste{read newton\bound{n1}}
}
\xtc{}{
\spadpaste{read vectors \bound{n1a}}
}

\xtc{
The cube root of two.
}{
\spadpaste{f := x**3 - 2\bound{n2}\free{n1 n1a}}
}
\xtc{
Get Newton's iteration formula.
}{
\spadpaste{g := newtonStep f\bound{n3}\free{n2}}
}
\xtc{
Let \spad{a} denote the result of
applying Newton's iteration once to the complex number \spad{1 + \%i}.
}{
\spadpaste{a := g(1.0 + \%i)\bound{n4}\free{n3}}
}
\xtc{
Now apply it repeatedly. How fast does it converge?
}{
\spadpaste{[(a := g(a)) for i in 1..]\bound{n5}\free{n4}}
}
\xtc{
Check the accuracy of the last iterate.
}{
\spadpaste{a**3\bound{n6}\free{n5}}
}

```

In

```

\downlink{'MappingPackage1'}{MappingPackageOneXmpPage}
\ignore{MappingPackage1},

```

we show how functions can be manipulated as objects in Axiom. A useful operation to consider here is `\spadop{*}`, which means composition. For example `\spad{g*g}` causes the Newton iteration formula to be applied twice. Correspondingly, `\spad{g**n}` means to apply the iteration formula `\spad{n}` times.

```

%
\xtc{

```

```

Apply \spad{g} twice to the point \spad{1 + \%i}.
}{
\spadpaste{(g*g) (1.0 + \%i)\bound{n10}\free{n3}}
}
\xtc{
Apply \spad{g} 11 times.
}{
\spadpaste{(g**11) (1.0 + \%i)\bound{n11}\free{n10}}
}

```

Look now at the vector field and surface generated after two steps of Newton's formula for the cube root of two. The poles in these pictures represent bad starting values, and the flat areas are the regions of convergence to the three roots.

```

%
\psXtc{

`\beginscroll`

Packages provide the bulk of
Axiom’s algorithmic library, from numeric packages for computing
special functions to symbolic facilities for
differential equations, symbolic integration, and limits.

In `\downlink{‘‘Interactive Programming’’}{ugIntProgPage}` in Chapter
10\ignore{ugIntProg}, we developed several useful
functions for drawing vector fields and complex functions. We now

show you how you can add these functions to the Axiom library to make them available for general use.

The way we created the functions in `\downlink{'Interactive Programming'}{ugIntProgPage}` in Chapter 10\ignore{ugIntProg} is typical of how you, as an advanced Axiom user, may interact with Axiom. You have an application. You go to your editor and create an input file defining some functions for the application. Then you run the file and try the functions. Once you get them all to work, you will often want to extend them, add new features, perhaps write additional functions.

Eventually, when you have a useful set of functions for your application, you may want to add them to your local Axiom library. To do this, you embed these function definitions in a package and add that package to the library.

To introduce new packages, categories, and domains into the system, you need to use the Axiom compiler to convert the constructors into executable machine code. An existing compiler in Axiom is available on an ‘as-is’ basis. A new, faster compiler will be available in version 2.0 of Axiom.

14.0.199 Names, Abbreviations, and File Structure

⇒ “notitle” (ugIntProgPage) 13.0.188 on page 2635

⇒ “notitle” (ugTypesWritingAbbrPage) 7.0.43 on page 1826

```

<ug11.ht>+≡
  \begin{page}{ugPackagesNamesPage}
  {11.1. Names, Abbreviations, and File Structure}
  \beginscroll
  %

```

Each package has a name and an abbreviation. For a package of the complex draw functions from

\downlink{‘‘Interactive Programming’’}{ugIntProgPage} in Chapter 10\ignore{ugIntProg}, we choose the name

\nonLibAxiomType{DrawComplex} and abbreviation

\nonLibAxiomType{DRAWCX}.\footnote{An abbreviation can be any string of between two and seven capital letters and digits, beginning with a letter. See

\downlink{‘‘Abbreviations’’}{ugTypesWritingAbbrPage} in

Section 2.5.5\ignore{ugTypesWritingAbbr} for more

information.} To be sure that you have not chosen a name or

abbreviation already used by the system, issue the system command

\spadcmd{show} for both the name and the abbreviation.

Once you have named the package and its abbreviation, you can choose any new filename you like with extension ‘‘{\bf \spadFileExt{}}’’ to hold the definition of your package. We choose the name {\bf drawpak\spadFileExt{}}. If your application involves more than one package, you can put them all in the same file. Axiom assumes no relationship between the name of a library file, and the name or abbreviation of a package.

Near the top of the ‘‘{\bf \spadFileExt{}}’’ file, list all the abbreviations for the packages using \spadcmd{abbrev}, each command beginning in column one. Macros giving names to Axiom expressions can also be placed near the top of the file. The macros are only usable from their point of definition until the end of the file.

Consider the definition of

\nonLibAxiomType{DrawComplex} in Figure \ref{fig-pak-cdraw}.

After the macro

definition

```
\begin{verbatim}
```

```
S      ==> Segment DoubleFloat
```

```
\end{verbatim}
the name
{\tt S} can be used in the file as a
shorthand for \axiomType{Segment DoubleFloat}.
\footnote{The interpreter also allows
{\tt macro} for macro definitions.}
The abbreviation command for the package
\begin{verbatim}
)abbrev package DRAWCX DrawComplex
\end{verbatim}
is given after the macros (although it could precede them).

\endscroll
\autobuttons
\end{page}
```

14.0.200 Syntax

```
<ug11.ht>+≡
\begin{page}{ugPackagesSyntaxPage}{11.2. Syntax}
\beginscroll
```

The definition of a package has the syntax:

```
\centerline{{\frenchspacing{\it PackageForm {\tt :}}
Exports\quad{\tt ==}\quad Implementation}}}
```

The syntax for defining a package

constructor is the same as that for defining any function in Axiom.

In practice, the definition extends over many lines so that this syntax is not practical. Also, the type of a package is expressed by the operator `\axiom{with}` `\spadkey{with}` followed by an explicit list of operations. A preferable way to write the definition of a package is with a `\axiom{where}` `\spadkey{where}` expression:

```
\beginImportant
```

The definition of a package usually has the form: \newline

```
{\tt%
{\it PackageForm} : Exports == Implementation where \newline
\texht{\hspace*{.75pc}}{\tab{3}} {\it optional type declarations}\newline
\texht{\hspace*{.75pc}}{\tab{3}} Exports == with \newline
\texht{\hspace*{2.0pc}}{\tab{6}} {\it list of exported operations}\newline
\texht{\hspace*{.75pc}}{\tab{3}} Implementation == add \newline
\texht{\hspace*{2.0pc}}{\tab{6}}
{\it list of function definitions for exported operations}
}
\endImportant
```

The `\axiomType{DrawComplex}` package takes no parameters and exports five operations, each a separate item of a `\spadgloss{pile}`.

Each operation is described as a `\spadgloss{declaration}`: a name, followed by a colon (`\axiomSyntax{:}`), followed by the type of the operation.

All operations have types expressed as `\spadglossSee{mappings}{mapping}` with the syntax

```
\centerline{{{\it}}
\centerline{{source\quad{\tt ->}\quad target}}
\centerline{{}}}
```

```
\endscroll
```

```
\autobuttons
```

```
\end{page}
```

14.0.201 Abstract Datatypes

⇒ “notitle” (ugIntProgCompFunsPage) 13.0.195 on page 2662

(ug11.ht)+≡

```
\begin{page}{ugPackagesAbstractPage}{11.3. Abstract Datatypes}
\beginscroll
```

A constructor as defined in Axiom is called an `\spadgloss{abstract datatype}` in the computer science literature. Abstract datatypes separate “specification” (what operations are provided) from “implementation” (how the operations are implemented). The `{\tt Exports}` (specification) part of a constructor is said to be “public” (it provides the user interface to the package) whereas the `{\tt Implementation}` part is “private” (information here is effectively hidden---programs cannot take advantage of it).

The `{\tt Exports}` part specifies what operations the package provides to users. As an author of a package, you must ensure that the `{\tt Implementation}` part provides a function for each operation in the `{\tt Exports}` part.
`\footnote{The \spadtype{DrawComplex} package enhances the facility described in \downlink{‘‘Drawing Complex Functions’’}{ugIntProgCompFunsPage} in Chapter 10.7\ignore{ugIntProgCompFuns}` by allowing a complex function to have arrows emanating from the surface to indicate the direction of the complex argument.}

An important difference between interactive programming and the use of packages is in the handling of global variables such as `\axiom{realSteps}` and `\axiom{imagSteps}`. In interactive programming, you simply change the values of variables by `\spadgloss{assignment}`. With packages, such variables are local to the package---their values can only be set using functions exported by the package. In our example package, we provide two functions `\fakeAxiomFun{setRealSteps}` and `\fakeAxiomFun{setImagSteps}` for this purpose.

Another local variable is `\axiom{clipValue}` which can be changed using the exported operation `\fakeAxiomFun{setClipValue}`. This value is referenced by the internal function `\fakeAxiomFun{clipFun}` that decides whether to use the computed value of the function at a point or, if the magnitude of that value is too large, the value assigned to `\axiom{clipValue}` (with the appropriate sign).

```
\endscroll
\autobuttons
```

\end{page}

14.0.202 Capsules

<ug11.ht>+≡

```
\begin{page}{ugPackagesCapsulesPage}{11.4. Capsules}
\beginscroll
%
The part to the right of {\tt add} in the {\tt Implementation}
\spadkey{add}
part of the definition is called a \spadgloss{capsule}.
The purpose of a capsule is:
\indent{4}
\beginitems
\item[-] to define a function for each exported operation, and
\item[-] to define a \spadgloss{local environment}
for these functions to run.
\enditems
\indent{0}
```

What is a local environment?

First, what is an environment?

Think of the capsule as an input file that Axiom reads from top to bottom.

Think of the input file as having a `\axiom{clear all}` at the top so that initially no variables or functions are defined.

When this file is read, variables such as `\axiom{realSteps}` and `\axiom{arrowSize}` in `\nonLibAxiomType{DrawComplex}` are set to initial values. Also, all the functions defined in the capsule are compiled. These include those that are exported (like `\axiom{drawComplex}`), and those that are not (like `\axiom{makeArrow}`).

At the end, you get a set of name-value pairs:

variable names (like `\axiom{realSteps}` and `\axiom{arrowSize}`) are paired with assigned values, while operation names (like `\axiom{drawComplex}` and `\axiom{makeArrow}`) are paired with function values.

This set of name-value pairs is called an `\spadgloss{environment}`. Actually, we call this environment the “initial environment” of a package: it is the environment that exists immediately after the package is first built. Afterwards, functions of this capsule can access or reset a variable in the environment. The environment is called `{\it local}` since any changes to the value of a variable in this environment can be seen `{\it only}` by these functions.

Only the functions from the package can change the variables in the local environment. When two functions are called successively from a package, any changes caused by the first function called are seen by

the second.

Since the environment is local to the package, its names don't get mixed up with others in the system or your workspace. If you happen to have a variable called `\axiom{realSteps}` in your workspace, it does not affect what the `\nonLibAxiomType{DrawComplex}` functions do in any way.

The functions in a package are compiled into machine code. Unlike function definitions in input files that may be compiled repeatedly as you use them with varying argument types, functions in packages have a unique type (generally parameterized by the argument parameters of a package) and a unique compilation residing on disk.

The capsule itself is turned into a compiled function. This so-called `{\it capsule function}` is what builds the initial environment spoken of above. If the package has arguments (see below), then each call to the package constructor with a distinct pair of arguments builds a distinct package, each with its own local environment.

```
\endscroll

\end{page}
```

14.0.203 Input Files vs. Packages

```

<ug11.ht>+≡
\begin{page}{ugPackagesInputFilesPage}{11.5. Input Files vs. Packages}
\beginscroll
%
A good question at this point would be
‘‘Is writing a package more difficult than writing an input file?’’

```

The programs in input files are designed for flexibility and ease-of-use. Axiom can usually work out all of your types as it reads your program and does the computations you request. Let's say that you define a one-argument function without giving its type. When you first apply the function to a value, this value is understood by Axiom as identifying the type for the argument parameter. Most of the time Axiom goes through the body of your function and figures out the target type that you have in mind. Axiom sometimes fails to get it right. Then---and only then---do you need a declaration to tell Axiom what type you want.

Input files are usually written to be read by Axiom---and by you. Without suitable documentation and declarations, your input files are likely incomprehensible to a colleague---and to you some months later!

Packages are designed for legibility, as well as run-time efficiency. There are few new concepts you need to learn to write packages. Rather, you just have to be explicit about types and type conversions. The types of all functions are pre-declared so that Axiom---and the reader--- knows precisely what types of arguments can be passed to and from the functions (certainly you don't want a colleague to guess or to have to work this out from context!). The types of local variables are also declared. Type conversions are explicit, never automatic.\footnote{There is one exception to this rule: conversions from a subdomain to a domain are automatic. After all, the objects both have the domain as a common type.}

In summary, packages are more tedious to write than input files. When writing input files, you can casually go ahead, giving some facts now, leaving others for later. Writing packages requires forethought, care and discipline.

%
```

Once you have defined the package `\nonLibAxiomType{DrawComplex}`, you need to compile and test it. To compile the package, issue the system command `\spadcmd{compile drawpak}`. Axiom reads the file `{\bf drawpak\spadFileExt{}}` and compiles its contents into machine binary. If all goes well, the file `{\bf DRAWCX.nrlib}` is created in your local directory for the package. To test the package, you must load the package before trying an operation.

```

14.0.205 Parameters

- ⇒ “notitle” (ugTypesPage) 7.0.35 on page 1795
- ⇒ “notitle” (ugUserBlocksPage) 10.0.113 on page 2130
- ⇒ “notitle” (ugCategoriesAttributesPage) 15.0.218 on page 2727

```

<ug11.ht>+≡
\begin{page}{ugPackagesParametersPage}{11.7. Parameters}
\beginscroll

```

The power of packages becomes evident when packages have parameters. Usually these parameters are domains and the exported operations have types involving these parameters.

In `\downlink{‘‘Using Types and Modes’’}{ugTypesPage}` in Chapter 2`\ignore{ugTypes}`, you learned that categories denote classes of domains. Although we cover this notion in detail in the next chapter, we now give you a sneak preview of its usefulness.

In `\downlink{‘‘Functions Defined with Blocks’’}{ugUserBlocksPage}` in Section 6.15`\ignore{ugUserBlocks}`, we defined functions `\axiom{bubbleSort(m)}` and `\axiom{insertionSort(m)}` to sort a list of integers. If you look at the code for these functions, you see that they may be used to sort `{\it any}` structure `\axiom{m}` with the right properties. Also, the functions can be used to sort lists of `{\it any}` elements---not just integers. Let us now recall the code for `\axiom{bubbleSort}`.

```

\begin{verbatim}
bubbleSort(m) ==
  n := #m
  for i in 1..(n-1) repeat
    for j in n..(i+1) by -1 repeat
      if m.j < m.(j-1) then swap!(m,j,j-1)
  m
\end{verbatim}

```

What properties of “lists of integers” are assumed by the sorting algorithm? In the first line, the operation `\spadfun{\#}` computes the maximum index of the list. The first obvious property is that `\axiom{m}` must have a finite number of elements. In Axiom, this is done by your telling Axiom that `\axiom{m}` has the “attribute” `\spadatt{finiteAggregate}`. An `\spadgloss{attribute}` is a property that a domain either has or does not have. As we show later in `\downlink{‘‘Attributes’’}{ugCategoriesAttributesPage}`

in Section 12.9\ignore{ugCategoriesAttributes}, programs can query domains as to the presence or absence of an attribute.

The operation `\spadfunX{swap}` swaps elements of `\axiom{m}`. Using `\Browse{}`, you find that `\spadfunX{swap}` requires its elements to come from a domain of category `\axiomType{IndexedAggregate}` with attribute `\spadatt{shallowlyMutable}`.

This attribute means that you can change the internal components of `\axiom{m}` without changing its external structure. Shallowly-mutable data structures include lists, streams, one- and two-dimensional arrays, vectors, and matrices.

The category `\axiomType{IndexedAggregate}` designates the class of aggregates whose elements can be accessed by the notation `\axiom{m.s}` for suitable selectors `\axiom{s}`.

The category `\axiomType{IndexedAggregate}` takes two arguments: `\axiom{Index}`, a domain of selectors for the aggregate, and `\axiom{Entry}`, a domain of entries for the aggregate. Since the sort functions access elements by integers, we must choose `\axiom{Index = } \axiomType{Integer}`.

The most general class of domains for which `\axiom{bubbleSort}` and `\axiom{insertionSort}` are defined are those of category `\spadtype{IndexedAggregate(Integer,Entry)}` with the two attributes `\spadatt{shallowlyMutable}` and `\spadatt{finiteAggregate}`.

Using `\Browse{}`, you can also discover that Axiom has many kinds of domains with attribute `\spadatt{shallowlyMutable}`. Those of class `\axiomType{IndexedAggregate(Integer,Entry)}` include `\axiomType{Bits}`, `\axiomType{FlexibleArray}`, `\axiomType{OneDimensionalArray}`, `\axiomType{List}`, `\axiomType{String}`, and `\axiomType{Vector}`, and also `\axiomType{HashTable}` and `\axiomType{EqTable}` with integer keys. Although you may never want to sort all such structures, we nonetheless demonstrate Axiom's ability to do so.

Another requirement is that `\nonLibAxiomType{Entry}` has an operation `\axiomOp{<}`. One way to get this operation is to assume that `\nonLibAxiomType{Entry}` has category `\axiomType{OrderedSet}`. By definition, will then export a `\axiomOp{<}` operation. A more general approach is to allow any comparison function `\axiom{f}` to be used for sorting. This function will be passed as an argument to the sorting functions.

Our sorting package then takes two arguments: a domain `\axiom{S}` of objects of `{\it any}` type, and a domain `\axiom{A}`, an aggregate of

type `\axiomType{IndexedAggregate(Integer, S)}` with the above two attributes. Here is its definition using what are close to the original definitions of `\axiom{bubbleSort}` and `\axiom{insertionSort}` for sorting lists of integers. The symbol `\axiomSyntax{!}` is added to the ends of the operation names. This uniform naming convention is used for Axiom operation names that destructively change one or more of their arguments.

14.0.206 Conditionals

⇒ “notitle” (ugUserBlocksPage) 10.0.113 on page 2130

```
<ug11.ht>+≡
\begin{page}{ugPackagesCondsPage}{11.8. Conditionals}
\beginscroll
```

When packages have parameters, you can say that an operation is or is not exported depending on the values of those parameters. When the domain of objects `\axiom{S}` has an `\axiomOp{<}` operation, we can supply one-argument versions of `\axiom{bubbleSort}` and `\axiom{insertionSort}` which use this operation for sorting. The presence of the operation `\axiomOp{<}` is guaranteed when `\axiom{S}` is an ordered set.

```
\beginImportant

\noindent
{\tt 1.\ \ \ \ Exports\ ==\ with}\newline
{\tt 2.\ \ \ \ \ \ \ \ bubbleSort!\ (A,(S,S)\ ->\ Boolean)\ ->\ A}
\newline
{\tt 3.\ \ \ \ \ \ \ \
insertionSort!\ (A,\ (S,S)\ ->\ Boolean)\ ->\ A}\newline
{\tt 4.\ \ \ \ }\newline
{\tt 5.\ \ \ \ \ \ \ \ \ if\ S\ has\ OrderedSet\ then}\newline
{\tt 6.\ \ \ \ \ \ \ \ \ \ bubbleSort!\ A\ ->\ A}\newline
{\tt 7.\ \ \ \ \ \ \ \ \ \ insertionSort!\ A\ ->\ A}\newline
\endImportant
```

In addition to exporting the one-argument sort operations conditionally, we must provide conditional definitions for the operations in the `{\tt Implementation}` part.

This is easy: just have the one-argument functions call the corresponding two-argument functions with the operation `\axiomOp{<}` from `\axiom{S}`.

```
\beginImportant

\noindent
{\tt 1.\ \ \ \ \ \ \ \ Implementation\ ==\ add}\newline
{\tt 2.\ \ \ \ \ \ \ \ \ \ \ \ \ \ ...}\newline
{\tt 3.\ \ \ \ \ \ \ \ \ if\ S\ has\ OrderedSet\ then}\newline
{\tt 4.\ \ \ \ \ \ \ \ \ \ \ \ \ \
bubbleSort!(m)\ ==\ bubbleSort!(m,<\$S)}\newline
```

```
{\tt 5.\ \ \ \ \ \ \ \ \ \ \
insertionSort!(m)\ ==\ insertionSort!(m,<\$S)}\newline
\endImportant
```

In `\downlink{'Functions Defined with Blocks'}\{ugUserBlocksPage}` in Section 6.15\ignore\{ugUserBlocks}, we give an alternative definition of `\fakeAxiomFun{bubbleSort}` using `\spadfunFrom{first}\{List}` and `\spadfunFrom{rest}\{List}` that is more efficient for a list (for which access to any element requires traversing the list from its first node). To implement a more efficient algorithm for lists, we need the operation `\spadfun{setelt}` which allows us to destructively change the `\spadfun{first}` and `\spadfun{rest}` of a list. Using `\Browse{}`, you find that these operations come from category `\axiomType{UnaryRecursiveAggregate}`. Several aggregate types are unary recursive aggregates including those of `\axiomType{List}` and `\axiomType{AssociationList}`. We provide two different implementations for `\fakeAxiomFun{bubbleSort!}` and `\fakeAxiomFun{insertionSort!}`: one for list-like structures, another for array-like structures.

\beginImportant

```
\noindent
{\tt 1.\ \ \ Implementation\ ==\ add}\newline
{\tt 2.\ \ \ \ \ \ \ \ \ \ \ ...}\newline
{\tt 3.\ \ \ \ \ \ \ if\ A\ has\ UnaryRecursiveAggregate(S)\ then}
\newline
{\tt 4.\ \ \ \ \ \ \ \ \ bubbleSort!(m,f�)\ ==}\newline
{\tt 5.\ \ \ \ \ \ \ \ \ \ empty?\ m\ =>\ m}\newline
{\tt 6.\ \ \ \ \ \ \ \ \ \ l\ :=\ m}\newline
{\tt 7.\ \ \ \ \ \ \ \ \ \ }
while\ not\ empty?\ (r\ :=\ l.rest)\ repeat}\newline
{\tt 8.\ \ \ \ \ \ \ \ \ \ r\ :=\ bubbleSort!\ r}\newline
{\tt 9.\ \ \ \ \ \ \ \ \ \ x\ :=\ l.first}\newline
{\tt 10.\ \ \ \ \ \ \ \ \ \ if\ fn(r.first,x)\ then}\newline
{\tt 11.\ \ \ \ \ \ \ \ \ \ l.first\ :=\ r.first}\newline
{\tt 12.\ \ \ \ \ \ \ \ \ \ r.first\ :=\ x}\newline
{\tt 13.\ \ \ \ \ \ \ \ \ \ l.rest\ :=\ r}\newline
{\tt 14.\ \ \ \ \ \ \ \ \ \ l\ :=\ l.rest}\newline
{\tt 15.\ \ \ \ \ \ \ \ \ \ m}\newline
{\tt 16.\ \ \ \ \ \ \ \ insertionSort!(m,f�)\ ==}\newline
{\tt 17.\ \ \ \ \ \ \ \ \ \ \ ...}\newline
\endImportant
```

The ordering of definitions is important.

The standard definitions come first and

Another equivalent way to write the capsule is to use an `\axiom{if-then-else}` expression:

```
\spadkey{if}
```

```
\noindent
{\tt 1.\ \ \ \ \ \ \ \ if\ A\ has\ UnaryRecursiveAggregate(S)\ then}
\newline
{\tt 2.\ \ \ \ \ \ \ \ \ \ \ ...}\newline
{\tt 3.\ \ \ \ \ \ \ \ else}\newline
{\tt 4.\ \ \ \ \ \ \ \ \ \ \ ...}\newline
\endImportant
```

```
\endscroll
\autobuttons
\end{page}
```

14.0.208 How Packages Work

⇒ “notitle” (ugCategoriesHierPage) 15.0.213 on page 2718

```

\ug11.ht\+=
\begin{page}{ugPackagesHowPage}{11.10. How Packages Work}
\beginscroll

```

Recall that packages as abstract datatypes are compiled independently and put into the library. The curious reader may ask: ‘How is the interpreter able to find an operation such as `\fakeAxiomFun{bubbleSort!}`? Also, how is a single compiled function such as `\fakeAxiomFun{bubbleSort!}` able to sort data of different types?’

After the interpreter loads the package `\nonLibAxiomType{SortPackage}`, the four operations from the package become known to the interpreter. Each of these operations is expressed as a `\it modemap` in which the type of the operation is written in terms of symbolic domains.

```

\nullXtc{
See the modemaps for \fakeAxiomFun{bubbleSort!}.
}{
\spadpaste{display op bubbleSort!}
}
\begin{verbatim}
There are 2 exposed functions called bubbleSort! :

```

```

[1] D1 -> D1 from SortPackage(D2,D1)
    if D2 has ORDSET and D2 has OBJECT and D1 has
    IndexedAggregate(Integer, D2) with
        finiteAggregate
        shallowlyMutable

[2] (D1,((D3,D3) -> Boolean)) -> D1 from SortPackage(D3,D1)
    if D3 has OBJECT and D1 has
    IndexedAggregate(Integer,D3) with
        finiteAggregate
        shallowlyMutable
\end{verbatim}

```

What happens if you ask for `\axiom{bubbleSort!([1,-5,3])}`?

There is a unique modemap for an operation named `\fakeAxiomFun{bubbleSort!}` with one argument.

Since `\axiom{[1,-5,3]}` is a list of integers, the symbolic domain

\axiom{D1} is defined as \axiomType{List(Integer)}.
 For some operation to apply, it must satisfy the predicate for
 some \axiom{D2}.
 What \axiom{D2}?
 The third expression of the \axiom{and} requires {\tt D1 has
 IndexedAggregate(Integer, D2) with} two attributes.
 So the interpreter searches for an \axiomType{IndexedAggregate}
 among the ancestors of \axiomType{List (Integer)} (see

\downlink{‘‘Hierarchies’’}{ugCategoriesHierPage} in Section
 12.4\ignore{ugCategoriesHier}). It finds one:
 \axiomType{IndexedAggregate(Integer, Integer)}. The interpreter tries
 defining \axiom{D2} as \axiomType{Integer}. After substituting for
 \axiom{D1} and \axiom{D2}, the predicate evaluates to \axiom{true}.
 An applicable operation has been found!

Now Axiom builds the package \axiomType{SortPackage(List(Integer),
 Integer)}. According to its definition, this package exports the
 required operation: \fakeAxiomFun{bubbleSort!}: \spadsig{List
 Integer}{List Integer}. The interpreter then asks the package for a
 function implementing this operation. The package gets all the
 functions it needs (for example, \axiomFun{rest} and \axiomFunX{swap})
 from the appropriate domains and then it returns a
 \fakeAxiomFun{bubbleSort!} to the interpreter together with the local
 environment for \fakeAxiomFun{bubbleSort!}. The interpreter applies
 the function to the argument \axiom{[[1,-5,3]]}. The
 \fakeAxiomFun{bubbleSort!} function is executed in its local
 environment and produces the result. \endscroll \autobuttons

\begin{page}{ugCategoriesPage}{12. Categories}
\beginscroll
```

This chapter unravels the mysteries of categories---what they are, how they are related to domains and packages, how they are defined in Axiom, and how you can extend the system to include new categories of your own.

We assume that you have read the introductory material on domains and categories in [\downlink{'Domain Constructors'}{ugTypesBasicDomainConsPage}](#) in Section 2.1.1~~\ignore{ugTypesBasicDomainCons}~~. There you learned that the notion of packages covered in the previous chapter are special cases of domains. While this is in fact the case, it is useful here to regard domains as distinct from packages.

Think of a domain as a datatype, a collection of objects (the objects of the domain). From your “sneak preview” in the previous chapter, you might conclude that categories are simply named clusters of operations exported by domains. As it turns out, categories have a much deeper meaning. Categories are fundamental to the design of Axiom. They control the interactions between domains and algorithmic packages, and, in fact, between all the components of Axiom.

Categories form hierarchies as shown on the inside cover pages of this book. The inside front-cover pages illustrate the basic algebraic hierarchy of the Axiom programming language. The inside back-cover pages show the hierarchy for data structures.

Think of the category structures of Axiom as a foundation for a city on which superstructures (domains) are built. The algebraic hierarchy, for example, serves as a foundation for constructive mathematical algorithms embedded in the domains of Axiom. Once in place, domains can be constructed, either independently or from one another.

Superstructures are built for quality---domains are compiled into machine code for run-time efficiency. You can extend the foundation in directions beyond the space directly beneath the superstructures, then extend selected superstructures to cover the space. Because of the compilation strategy, changing components of the foundation generally means that the existing superstructures (domains) built on the changed parts of the foundation (categories) have to be rebuilt---that is, recompiled.

Before delving into some of the interesting facts about categories, let’s see how you define them in Axiom.

15.0.210 Definitions

\Leftarrow “Categories” (ugCategoriesPage) 15.0.209 on page 2709
 \Rightarrow “notitle” (ugTypesPage) 7.0.35 on page 1795

$$\langle ug12.ht \rangle + \equiv$$

```
\begin{page}{ugCategoriesDefsPage}{12.1. Definitions}
\beginscroll
```

A category is defined by a function with exactly the same format as any other function in Axiom.

```
\beginImportant
The definition of a category has the syntax:
\centerline{{{\it CategoryForm} : {\tt Category}\quad{}}==\quad{}}
{{\it Extensions} {\tt [ with} {\it Exports} {\tt ]}}}
```

The brackets {\tt []} here indicate optionality.
\endImportant

The first example of a category definition is `\spadtype{SetCategory}`, the most basic of the algebraic categories in Axiom.

```
\beginImportant
\noindent
{\tt 1.\ \ \ SetCategory():\ Category\ ==}\newline
{\tt 2.\ \ \ \ \ Join(Type,CoercibleTo\ OutputForm)\ with}\newline
{\tt 3.\ \ \ \ \ \ \ \ \ "="\ :\ (\$, \$)\ ->\ Boolean}\newline
\endImportant
```

The definition starts off with the name of the category (`\spadtype{SetCategory}`); this is always in column one in the source file.

%% maybe talk about naming conventions for source files? .spad or .ax?

All parts of a category definition are then indented with respect to this first line.

In `\downlink{‘‘Using Types and Modes’’}{ugTypesPage}` in Chapter 2\ignore{ugTypes}, we talked about `\spadtype{Ring}` as denoting the class of all domains that are rings, in short, the class of all rings. While this is the usual naming convention in Axiom, it is also common to use the word ‘‘Category’’ at the end of a category

name for clarity. The interpretation of the name `\spadtype{SetCategory}` is, then, “the category of all domains that are (mathematical) sets.”

The name `\spadtype{SetCategory}` is followed in the definition by its formal parameters enclosed in parentheses `\spadSyntax{()}`.

Here there are no parameters.

As required, the type of the result of this category function is the distinguished name `\sf Category`.

Then comes the `\spadSyntax{==}`.

As usual, what appears to the right of the `\spadSyntax{==}` is a definition, here, a category definition.

A category definition always has two parts separated by the reserved word

`\spadkey{with}`

`\spad{with}`.

`%\footnote{Debugging hint: it is very easy to forget`

`%the \spad{with}!}`

The first part tells what categories the category extends.

Here, the category extends two categories: `\spadtype{Type}`, the category of all domains, and

`\spadtype{CoercibleTo(OutputForm)}`.

`%\footnote{\spadtype{CoercibleTo(OutputForm)}`

`%can also be written (and is written in the definition above) without %parentheses.}`

The operation `\spad{Join}` is a system-defined operation that

`\spadkey{Join}`

forms a single category from two or more other categories.

Every category other than `\spadtype{Type}` is an extension of some other category.

If, for example, `\spadtype{SetCategory}` extended only the category `\spadtype{Type}`, the definition here would read “`{\tt Type with ...}`”.

In fact, the `{\tt Type}` is optional in this line; “`{\tt with ...}`” suffices.

`\endscroll`

`\autobuttons`

`\end{page}`

15.0.211 Exports

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

```
<ug12.ht>+≡
\begin{page}{ugCategoriesExportsPage}{12.2. Exports}
\beginscroll
```

To the right of the `\spad{with}` is a list of
`\spadkey{with}`
all the `\spadglossSee{exports}{export}` of the category.
Each exported operation has a name and a type expressed by a
`\spadgloss{declaration}` of the form
`‘‘{\frenchspacing\tt {\it name}: {\it type}}’’`.

Categories can export symbols, as well as
`{\tt 0}` and `{\tt 1}` which denote
domain constants.\footnote{The
numbers `{\tt 0}` and `{\tt 1}` are operation names in Axiom.}
In the current implementation, all other exports are operations with
types expressed as `\spadglossSee{mappings}{mapping}` with the syntax
`\centerline{{{\it}}}`
`\centerline{{source}\quad{\tt ->}\quad target}}`
`\centerline{{}}}`

The category `\spadtype{SetCategory}` has a single export: the operation
`\spadop{=}` whose type is given by the mapping `{\tt (\$, \$) -> Boolean}`.
The `\spadSyntax{\$}` in a mapping type always means ‘‘the domain.’’ Thus
the operation `\spadop{=}` takes two arguments from the domain and
returns a value of type `\spadtype{Boolean}`.

The source part of the mapping here is given by a `{\it tuple}`
consisting of two or more types separated by commas and enclosed in
parentheses.
If an operation takes only one argument, you can drop the parentheses
around the source type.
If the mapping has no arguments, the source part of the mapping is either
left blank or written as `\spadSyntax{()}`.
Here are examples of formats of various operations with some
contrived names.

```
\begin{verbatim}
someIntegerConstant :    $
aZeroArgumentOperation:  () -> Integer
aOneArgumentOperation:   Integer -> $
```

```
aTwoArgumentOperation:    (Integer,$) -> Void
aThreeArgumentOperation:  ($,Integer,$) -> Fraction($)
\end{verbatim}

\endscroll
\autobuttons
\end{page}
```

15.0.212 Documentation

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

`<ug12.ht>+≡`

```
\begin{page}{ugCategoriesDocPage}{12.3. Documentation}
\beginscroll
```

The definition of `\spadtype{SetCategory}` above is missing an important component: its library documentation. Here is its definition, complete with documentation.

```
\beginImportant
\noindent
{\tt 1.\ \ \ \ ++\ Description:}\newline
{\tt 2.\ \ \ \ ++\
\bs{axiomType}\{SetCategory}\ \ is\ the\ basic\ category}\newline
{\tt 3.\ \ \ \ ++\
for\ describing\ a\ collection\ of\ elements\ with}\newline
{\tt 4.\ \ \ \ ++\

{\tt 11.\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ ++\ \bs{axiom}\{y\}\ are\ equal.}\newline
\endImportant
```

Documentary comments are an important part of constructor definitions. Documentation is given both for the category itself and for each export.

A description for the category precedes the code.

Each line of the description begins in column one with `\axiomSyntax{++}`. The description starts with the word `{\tt Description:}`. `\footnote{Other` information such as the author’s name, date of creation, and so on, can go in this

area as well but are currently ignored by Axiom.}

All lines of the description following the initial line are indented by the same amount.

`{\texht{\sloppy}{}}` Surround the name of any constructor (with or

without parameters) with an
`\texht{\verb+axiomType{}}+\{\}\axiomType\{\}`. Similarly, surround an
operator name with `\texht{\verb+axiomOp{}}+\{\}\axiomOp\{\}`, an Axiom
operation with `\texht{\verb+axiomFun{}}+\{\}\axiomFun\{\}`, and a
variable or Axiom expression with
`\texht{\verb+axiom{}}+\{\}\axiom\{\}`. Library documentation is given
in a `\TeX{}`-like language so that it can be used both for hard-copy
and for `\Browse{}`. These different wrappings cause operations and
types to have mouse-active buttons in `\Browse{}`. For hard-copy
output, wrapped expressions appear in a different font. The above
documentation appears in hard-copy as:

```

}
%
\texht{\begin{quotation}}{\indent{3}}
%
\axiomType{SetCategory} is the basic category
for describing a collection of elements with \axiomOp{=}
(equality) and a \spadfun{coerce} to \axiomType{OutputForm}.
%
\texht{\end{quotation}}{\indent{0}}
%
and
%
\texht{\begin{quotation}}{\indent{3}}
%
\axiom{x = y} tests if \axiom{x} and \axiom{y} are equal.
%
\texht{\end{quotation}}{\indent{0}}
%
```

For our purposes in this chapter, we omit the documentation from further
category descriptions.

```

\endscroll
\autobuttons
\end{page}
```

15.0.213 Hierarchies

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

`<ug12.ht>+≡`

```
\begin{page}{ugCategoriesHierPage}{12.4. Hierarchies}
\beginscroll
```

A second example of a category is
`\spadtype{SemiGroup}`, defined by:

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ SemiGroup():\ Category\ ==\ SetCategory\ with}\newline
{\tt 2.\ \ \ \ \ \ \ \ \ \ \ \ "*" :\ \ (\$, \$)\ ->\ \$}\newline
{\tt 3.\ \ \ \ \ \ \ \ \ \ \ \ "**" :\ (\$, \ PositiveInteger)\ ->\ \$}\newline
\endImportant
```

This definition is as simple as that for `\spadtype{SetCategory}`, except that there are two exported operations.

Multiple exported operations are written as a `\spadgloss{pile}`, that is, they all begin in the same column.

Here you see that the category mentions another type, `\spadtype{PositiveInteger}`, in a signature.

Any domain can be used in a signature.

Since categories extend one another, they form hierarchies.

Each category other than `\spadtype{Type}` has one or more parents given by the one or more categories mentioned before the `\spad{with}` part of the definition.

`\spadtype{SemiGroup}` extends `\spadtype{SetCategory}` and

`\spadtype{SetCategory}` extends both `\spadtype{Type}` and

`\spadtype{CoercibleTo (OutputForm)}`.

Since `\spadtype{CoercibleTo (OutputForm)}` also extends `\spadtype{Type}`, the mention of `\spadtype{Type}` in the definition is unnecessary but included for emphasis.

```
\endscroll
```

```
\autobuttons
```

```
\end{page}
```

15.0.214 Membership

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

```
<ug12.ht>+≡
\begin{page}{ugCategoriesMembershipPage}{12.5. Membership}
\beginscroll
```

We say a category designates a class of domains.
 What class of domains?
 That is, how does Axiom know what domains belong to what categories?
 The simple answer to this basic question is key to the design of
 Axiom:

```
\beginImportant
\centerline{{\bf Domains belong to categories by assertion.}}}
\endImportant
```

When a domain is defined, it is asserted to belong to one or more categories.
 Suppose, for example, that an author of domain `\spadtype{String}` wishes to use the binary operator `\spadop{*}` to denote concatenation.
 Thus `\spad{"hello " * "there"}` would produce the string `\spad{"hello there"}`
`\spad{"hello there"}\footnote{Actually, concatenation of strings in Axiom is done by juxtaposition or by using the operation \spadfunFrom{concat}{String}.`
 The expression `\spad{"hello " "there"}` produces the string `\spad{"hello there"}`.
 The author of `\spadtype{String}` could then assert that `\spadtype{String}` is a member of `\spadtype{SemiGroup}`.
 According to our definition of `\spadtype{SemiGroup}`, strings would then also have the operation `\spadop{**}` defined automatically.
 Then `\spad{"--" ** 4}` would produce a string of eight dashes `\spad{"-----"}`.
 Since `\spadtype{String}` is a member of `\spadtype{SemiGroup}`, it also is a member of `\spadtype{SetCategory}` and thus has an operation `\spadop{=}` for testing that two strings are equal.

```
\texht{Now turn to the algebraic category hierarchy inside the
front cover of this book.}{}
```

Any domain that is a member of a
 category extending `\spadtype{SemiGroup}` is a member of
`\spadtype{SemiGroup}` (that is, it `\it is` a semigroup).
 In particular, any domain asserted to be a `\spadtype{Ring}` is a
 semigroup since `\spadtype{Ring}` extends `\spadtype{Monoid}`, that,

in turn, extends `\spadtype{SemiGroup}`.
The definition of `\spadtype{Integer}` in Axiom asserts that
`\spadtype{Integer}` is a member of category
`\spadtype{IntegerNumberSystem}`, that, in turn, asserts that it is
a member of `\spadtype{EuclideanDomain}`.
Now `\spadtype{EuclideanDomain}` extends
`\spadtype{PrincipalIdealDomain}` and so on.
If you trace up the hierarchy, you see that
`\spadtype{EuclideanDomain}` extends `\spadtype{Ring}`, and,
therefore, `\spadtype{SemiGroup}`.
Thus `\spadtype{Integer}` is a semigroup and also exports the
operations `\spadop{*}` and `\spadop{**}`.

`\endscroll`
`\autobuttons`
`\end{page}`

$\langle uq12.ht \rangle_+ \equiv$

We actually omitted the last part of the definition of `\spadtype{SemiGroup}` in `\downlink{'Hierarchies'}{ugCategoriesHierPage}` in Section 12.4\ignore{ugCategoriesHier}. Here now is its complete Axiom definition.

\noindent

The `\spad{add}` part at the end is used to give ‘‘default definitions’’ for `\spadkey{add}` exported operations. Once you have a multiplication operation `\spadop{*}`, you can define exponentiation for positive integer exponents using repeated multiplication:

definition for `\spadop{**}` is called a `{\it default}` definition. In general, a category can give default definitions for any operation it exports. Since `\spadtype{SemiGroup}` and all its category descendants in the hierarchy export `\spadop{**}`, any descendant category may redefine `\spadop{**}` as well.

A domain of category `\spadtype{SemiGroup}` (such as `\spadtype{Integer}`) may or may not choose to define its own `\spadop{**}` operation. If it does not, a default definition that is closest (in a ‘tree-distance’ sense of the hierarchy) to the domain is chosen.

The part of the category definition following an `\spadop{add}` operation is a `\spadgloss{capsule}`, as discussed in `\texht{the previous chapter.}`
`{\downlink{'Packages'}}{ugPackagesPage}`
in Chapter 11`\ignore{ugPackages}.}`

The line

```
\begin{verbatim}
```

```
import RepeatedSquaring($)
```

```
\end{verbatim}
```

references the package

`\spadtype{RepeatedSquaring(\$)}`, that is, the package

`\spadtype{RepeatedSquaring}` that takes “this domain” as its parameter.

For example, if the semigroup `\spadtype{Polynomial (Integer)}`

does not define its own exponentiation operation, the

definition used may come from the package

`\spadtype{RepeatedSquaring (Polynomial (Integer))}`.

The next line gives the definition in terms of `\spadfun{expt}` from that package.

The default definitions are collected to form a “default package” for the category. The name of the package is the same as the category but with an ampersand (`\spadSyntax{&}`) added at the end. A default package always takes an additional argument relative to the category. Here is the definition of the default package `\pspadtype{SemiGroup\&}` as automatically generated by Axiom from the above definition of `\spadtype{SemiGroup}`.

15.0.216 Axioms

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709
 ⇒ “Defaults” (ugCategoriesDefaultsPage) 15.0.215 on page 2721

```
<ug12.ht>+≡
\begin{page}{ugCategoriesAxiomsPage}{12.7. Axioms}
\beginscroll
```

In \texht{the previous section}
 {\downlink{‘‘Defaults’’}{ugCategoriesDefaultsPage}
 in Section 12.6\ignore{ugCategoriesDefaults}}
 you saw the complete Axiom program defining \index{axiom}
 \spadtype{SemiGroup}. According to this definition, semigroups (that
 is, are sets with the operations \spadopFrom{*}{SemiGroup} and
 \spadopFrom{**}{SemiGroup}.

You might ask: ‘‘Aside from the notion of default packages, isn’t a
 category just a \spadgloss{macro}, that is, a shorthand equivalent to
 the two operations \spadop{*} and \spadop{**} with their types?’’ If a
 category were a macro, every time you saw the word
 \spadtype{SemiGroup}, you would rewrite it by its list of exported
 operations. Furthermore, every time you saw the exported operations
 of \spadtype{SemiGroup} among the exports of a constructor, you could
 conclude that the constructor exported \spadtype{SemiGroup}.

A category is {\it not} a macro and here is why.
 The definition for \spadtype{SemiGroup} has documentation that states:

```
\texht{\begin{quotation}}{\indent{3}}
  Category \spadtype{SemiGroup} denotes the class of all multiplicative
  semigroups, that is, a set with an associative operation \spadop{*}.

\texht{\vskip .5\baselineskip}{
{Axioms:}

  {\small\tt associative("*" : (\$, \$)->\$) -- (x*y)*z = x*(y*z)}
\texht{\end{quotation}}{\indent{3}}
```

According to the author’s remarks, the mere exporting of an operation
 named \spadop{*} and \spadop{**} is not enough to qualify the domain
 as a \spadtype{SemiGroup}. In fact, a domain can be a semigroup only
 if it explicitly exports a \spadop{**} and a \spadop{*} satisfying the
 associativity axiom.

In general, a category name implies a set of axioms, even mathematical theorems. There are numerous axioms from `\spadtype{Ring}`, for example, that are well-understood from the literature. No attempt is made to list them all. Nonetheless, all such mathematical facts are implicit by the use of the name `\spadtype{Ring}`.

```
\endscroll  
\autobuttons  
\end{page}
```

15.0.217 Correctness

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

```
<ug12.ht>+=
\begin{page}{ugCategoriesCorrectnessPage}{12.8. Correctness}
\beginscroll
```

While such statements are only comments,
 Axiom can enforce their intention simply by shifting the burden of
 responsibility onto the author of a domain.
 A domain belongs to category `\spad{Ring}` only if the
 author asserts that the domain belongs to `\spadtype{Ring}` or
 to a category that extends `\spadtype{Ring}`.

This principle of assertion is important for large user-extendable
 systems.
 Axiom has a large library of operations offering facilities in
 many areas.
 Names such as `\spadfun{norm}` and `\spadfun{product}`, for example, have
 diverse meanings in diverse contexts.
 An inescapable hindrance to users would be to force those who wish to
 extend Axiom to always invent new names for operations.
 %>> I don't think disambiguate is really a word, though I like it
 Axiom allows you to reuse names, and then use context to disambiguate one
 from another.

Here is another example of why this is important. Some languages,
 such as `{\bf APL}`, denote the `\spadtype{Boolean}` constants `\spad{true}`
 and `\spad{false}` by the integers `\spad{1}` and `\spad{0}`. You may want
 to let infix operators `\spadop{+}` and `\spadop{*}` serve as the logical
 operators `\spadfun{or}` and `\spadfun{and}`, respectively. But note
 this: `\spadtype{Boolean}` is not a ring. The `{\it inverse axiom}` for
`\spadtype{Ring}` states:

```
\centerline{
{Every element \spad{x} has an additive inverse \spad{y} such that}}
\centerline{{\spad{x + y = 0}.}}
%
\spadtype{Boolean} is not a ring since \spad{true} has
no inverse---there is no inverse element \spad{a} such that
\spad{1 + a = 0} (in terms of booleans, \spad{(true or a) = false}).
Nonetheless, Axiom {\it could} easily and correctly implement
\spadtype{Boolean} this way.
\spadtype{Boolean} simply would not assert that it is of category
```

`\spadtype{Ring}`.

Thus the `\spadop{+}` for `\spadtype{Boolean}` values is not confused with the one for `\spadtype{Ring}`.

Since the `\spadtype{Polynomial}` constructor requires its argument to be a ring, Axiom would then refuse to build the domain `\spadtype{Polynomial(Boolean)}`. Also, Axiom would refuse to wrongfully apply algorithms to `\spadtype{Boolean}` elements that presume that the ring axioms for `\spadop{+}` hold.

`\endscroll`

`\autobuttons`

`\end{page}`

15.0.218 Attributes

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

⇒ “Category Assertions” (ugDomainsAssertionsPage) 16.0.225 on page 2743

(ug12.ht)+≡

```
\begin{page}{ugCategoriesAttributesPage}{12.9. Attributes}
\beginscroll
```

Most axioms are not computationally useful.

Those that are can be explicitly expressed by what Axiom calls an `\spadgloss{attribute}`.

The attribute `\spadatt{commutative("*")}`, for example, is used to assert that a domain has commutative multiplication.

Its definition is given by its documentation:

```
\texht{\begingroup \parindent=1pc \narrower\noindent}{\indent{3}}%
  A domain \spad{R} has \spadatt{commutative("*")}
  if it has an operation " ": \spadsig{(R,R)}{R}
  such that \spad{x * y = y * x}.
\texht{\par\endgroup}{\indent{0}}
```

Just as you can test whether a domain has the category `\spadtype{Ring}`, you can test that a domain has a given attribute.

```
\xhc{
Do polynomials over the integers
have commutative multiplication?
}{
\spadpaste{Polynomial Integer has commutative("*")}
}
\xhc{
Do matrices over the integers
have commutative multiplication?
}{
\spadpaste{Matrix Integer has commutative("*")}
}
```

Attributes are used to conditionally export and define operations for a domain (see

`\downlink{'Category Assertions'}{ugDomainsAssertionsPage}` in Section 13.3\ignore{ugDomainsAssertions}).

Attributes can also be asserted in a category definition.

After mentioning category `\spadtype{Ring}` many times in this book,

it is high time that we show you its definition:

```
\beginImportant
\noindent
{\tt 1.\ \ \ Ring():\ Category\ ==}\newline
{\tt 2.\ \ \ \ \ Join(Rng,Monoid,LeftModule(\$: \ Rng))\ with}\newline
{\tt 3.\ \ \ \ \ \ \ \ \ \ \ characteristic:\ ->\ NonNegativeInteger}\newline
{\tt 4.\ \ \ \ \ \ \ \ \ \ \ coerce:\ Integer\ ->\ \$}\newline
{\tt 5.\ \ \ \ \ \ \ \ \ \ \ unitsKnown}\newline
{\tt 6.\ \ \ \ \ \ \ \ \ \ \ add}\newline
{\tt 7.\ \ \ \ \ \ \ \ \ \ \ n:Integer}\newline
{\tt 8.\ \ \ \ \ \ \ \ \ \ \ coerce(n)\ ==\ n\ *\ 1\$\$}\newline
\endImportant
```

There are only two new things here. First, look at the `\spadSyntax{\$ \$}` on the last line. This is not a typographic error! The first `\spadSyntax{\$}` says that the `\spad{1}` is to come from some domain. The second `\spadSyntax{\$}` says that the domain is ‘‘this domain.’’ If `\spadSyntax{\$}` is `\spadtype{Fraction(Integer)}`, this line reads `{\tt coerce(n) == n * 1\Fraction(Integer)}`.

The second new thing is the presence of attribute ‘‘`\spad{unitsKnown}`’’. Axiom can always distinguish an attribute from an operation. An operation has a name and a type. An attribute has no type. The attribute `\spadatt{unitsKnown}` asserts a rather subtle mathematical fact that is normally taken for granted when working with rings.\footnote{With this axiom, the units of a domain are the set of elements `\spad{x}` that each have a multiplicative inverse `\spad{y}` in the domain. Thus `\spad{1}` and `\spad{-1}` are units in domain `\spadtype{Integer}`. Also, for `\spadtype{Fraction Integer}`, the domain of rational numbers, all non-zero elements are units.} Because programs can test for this attribute, Axiom can correctly handle rather more complicated mathematical structures (ones that are similar to rings but do not have this attribute).

15.0.219 Parameters

⇐ “Categories” (ugCategoriesPage) 15.0.209 on page 2709

`<ug12.ht>+≡`

```
\begin{page}{ugCategoriesParametersPage}{12.10. Parameters}
\beginscroll
```

Like domain constructors, category constructors can also have parameters. For example, category `\spadtype{MatrixCategory}` is a parameterized category for defining matrices over a ring `\spad{R}` so that the matrix domains can have different representations and indexing schemes. Its definition has the form:

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ MatrixCategory(R,Row,Col):\ Category\ ==}\newline
{\tt 2.\ \ \ \ \ \ \ TwoDimensionalArrayCategory(R,Row,Col)\ with\ ...}\newline
\endImportant
```

The category extends `\spadtype{TwoDimensionalArrayCategory}` with the same arguments. You cannot find `\spadtype{TwoDimensionalArrayCategory}` in the algebraic hierarchy listing. Rather, it is a member of the data structure hierarchy, given inside the back cover of this book. In particular, `\spadtype{TwoDimensionalArrayCategory}` is an extension of `\spadtype{HomogeneousAggregate}` since its elements are all one type.

The domain `\spadtype{Matrix(R)}`, the class of matrices with coefficients from domain `\spad{R}`, asserts that it is a member of category `\spadtype{MatrixCategory(R, Vector(R), Vector(R))}`. The parameters of a category must also have types. The first parameter to `\spadtype{MatrixCategory}` `\spad{R}` is required to be a ring. The second and third are required to be domains of category `\spadtype{FiniteLinearAggregate(R)}`.^{\footnote{% This is another extension of `\spadtype{HomogeneousAggregate}` that you can see in the data structure hierarchy.}} In practice, examples of categories having parameters other than domains are rare.

Adding the declarations for parameters to the definition for `\spadtype{MatrixCategory}`, we have:

\beginImportant

\noindent

{\tt 1.\ \ \ R:\ Ring}\newline

{\tt 2.\ \ \ (Row,\ Col):\ FiniteLinearAggregate(R)}\newline

{\tt 3.\ \ \ }\newline

{\tt 4.\ \ \ MatrixCategory(R,\ Row,\ Col):\ Category\ ==}\newline

{\tt 5.\ \ \ \ \ \ \ }

TwoDimensionalArrayCategory(R,\ Row,\ Col)\ with\ ...}\newline

\endImportant

\endscroll

\autobuttons

\end{page}

15.0.220 Conditionals

\Leftarrow “Categories” (ugCategoriesPage) 15.0.209 on page 2709
 \Rightarrow “Conditionals” (ugPackagesCondsPage) 14.0.206 on page 2696

```

\begin{page}{ugCategoriesConditionalsPage}{12.11. Conditionals}
\beginscroll

```

As categories have parameters, the actual operations exported by a category can depend on these parameters.

As an example, the operation `\spadfunFrom{determinant}{MatrixCategory}` from category `\spadtype{MatrixCategory}` is only exported when the underlying domain `\spad{R}` has commutative multiplication:

```
\begin{verbatim}
if R has commutative("*") then
  determinant: $ -> R
\end{verbatim}
```

Conditionals can also define conditional extensions of a category. Here is a portion of the definition of `\spadtype{QuotientFieldCategory}`:

$$\begin{aligned} & \text{QuotientFieldCategory}(R) \text{ : Category} \Rightarrow \dots \text{ with } \dots \\ & \text{if } R \text{ has OrderedSet then OrderedSet} \\ & \text{if } R \text{ has IntegerNumberSystem then} \\ & \text{ceiling: } \$ \rightarrow R \\ & \dots \end{aligned}$$

Think of category `\spadtype{QuotientFieldCategory(R)}` as denoting the domain `\spadtype{Fraction(R)}`, the class of all fractions of the form `\smath{a/b}` for elements of `\spad{R}`. The first conditional means in English:
 “If the elements of `\spad{R}` are totally ordered (`\spad{R}` is an `\spadtype{OrderedSet}`), then so are the fractions `\smath{a/b}`”.

The second conditional is used to conditionally export an operation `\spadfun{ceiling}` which returns the smallest integer greater than or equal to its argument. Clearly, “ceiling” makes sense for integers but not for polynomials and other algebraic structures.

Because of this conditional,
the domain `\spadtype{Fraction(Integer)}` exports
an operation
`\spadfun{ceiling}: \spadsig{Fraction Integer}{Integer}`, but
`\spadtype{Fraction Polynomial Integer}` does not.

Conditionals can also appear in the default definitions for the
operations of a category.
For example, a default definition for `\spadfunFrom{ceiling}{Field}`
within the part following the `\spadop{add}` reads:

```
\begin{verbatim}
if R has IntegerNumberSystem then
    ceiling x == ...
\end{verbatim}
```

Here the predicate used is identical to the predicate in the `{\tt Exports}` part. This need not be the case. See
`\downlink{'Conditionals'}{ugPackagesCondsPage}` in Section
11.8\ignore{ugPackagesConds} for a more complicated
example.

```
\endscroll
\autobuttons
\end{page}
```

15.0.221 Anonymous Categories

\Leftarrow “Categories” (ugCategoriesPage) 15.0.209 on page 2709
 \Rightarrow “Abstract Datatypes” (ugPackagesAbstractPage) 14.0.201 on page 2683

```

\begin{page}{ugCategoriesAndPackagesPage}{12.12. Anonymous Categories}
\beginscroll

```

The part of a category to the right of a `{\tt with}` is also regarded as a category---an “anonymous category.” Thus you have already seen a category definition The `{\tt Exports}` part of the package `\pspatype{DrawComplex}` (`\downlink{‘‘Abstract Datatypes’’}{ugPackagesAbstractPage}` in Section 11.3`\ignore{ugPackagesAbstract}`) is an anonymous category. This is not necessary. We could, instead, give this category a name:

```
%
\beginImportant

\noindent
{\tt 1.\ \ \ DrawComplexCategory():\ Category\ ==\ with}\newline
{\tt 2.\ \ \ \ \ \ }
drawComplex:\ (C\ ->\ C,S,S,Boolean)\ ->\ VIEW3D}\newline
{\tt 3.\ \ \ \ \ \ }
drawComplexVectorField:\ (C\ ->\ C,S,S)\ ->\ VIEW3D}\newline
{\tt 4.\ \ \ \ \ \ setRealSteps:\ INT\ ->\ INT}\newline
{\tt 5.\ \ \ \ \ \ setImagSteps:\ INT\ ->\ INT}\newline
{\tt 6.\ \ \ \ \ \ setClipValue:\ DFLOAT->\ DFLOAT}\newline
\endImportant

%
and then define \spadtype{DrawComplex} by:
%
\beginImportant

\noindent
{\tt 1.\ \ \ DrawComplex():\ DrawComplexCategory\ ==\ Implementation}\newline
{\tt 2.\ \ \ \ \ \ where}\newline
{\tt 3.\ \ \ \ \ \ \ \ \ ...}\newline
\endImportant

%
```

There is no reason, however, to give this list of exports a name

since no other domain or package exports it.
In fact, it is rare for a package to export a named category.
As you will see in the next chapter, however, it is very common
for the definition of domains to mention one or more category
before the `{\tt with}`.

16.0.223 Domains vs. Packages

⇒ “notitle” (ugPackagesPage) 14.0.198 on page 2677

```
<ug13.ht>+≡
\begin{page}{ugPackagesDomsPage}{13.1. Domains vs. Packages}
\beginscroll
```

Packages are special cases of domains. What is the difference between a package and a domain that is not a package? By definition, there is only one difference: a domain that is not a package has the symbol `\axiomSyntax{\$}` appearing somewhere among the types of its exported operations. The `\axiomSyntax{\$}` denotes “this domain.” If the `\axiomSyntax{\$}` appears before the `\axiomSyntax{->}` in the type of a signature, it means the operation takes an element from the domain as an argument. If it appears after the `\axiomSyntax{->}`, then the operation returns an element of the domain.

If no exported operations mention `\axiomSyntax{\$}`, then evidently there is nothing of interest to do with the objects of the domain. You might then say that a package is a “boring” domain! But, as you saw in `\downlink{‘‘Packages’’}{ugPackagesPage}` in Chapter 11`\ignore{ugPackages}`, packages are a very useful notion indeed. The exported operations of a package depend solely on the parameters to the package constructor and other explicit domains.

To summarize, domain constructors are versatile structures that serve two distinct practical purposes: Those like `\axiomType{Polynomial}` and `\axiomType{List}` describe classes of computational objects; others, like `\pspadtype{SortPackage}`, describe packages of useful operations. As in the last chapter, we focus here on the first kind.

\caption{The \protect\axiomType{QuadraticForm} domain.}\label{fig-quadform}
\endImportant

```

A domain constructor can take any number and type of parameters.
`\axiomType{QuadraticForm}` takes a positive integer `\axiom{n}` and a field `\axiom{K}` as arguments.
Like a package, a domain has a set of explicit exports and an

implementation described by a capsule.

Domain constructors are documented in the same way as package constructors.

Domain `\axiomType{QuadraticForm(n, K)}`, for a given positive integer `\axiom{n}` and domain `\axiom{K}`, explicitly exports three operations:

```
%
\indent{4}
\beginitems
\item\axiom{quadraticForm(A)} creates a quadratic form from a matrix
\axiom{A}.
\item\axiom{matrix(q)} returns the matrix \axiom{A} used to create
the quadratic form \axiom{q}.
\item\axiom{q.v} computes the scalar  $\text{transpose}(v) \cdot A \cdot v$ 
for a given vector \axiom{v}.
\enditems
\indent{0}
```

Compared with the corresponding syntax given for the definition of a package, you see that a domain constructor has three optional parts to its definition: `{\it Category Assertions}`, `{\it Add Domain}`, and `{\it Representation}`.

```
\endscroll
\autobuttons
\end{page}
```

16.0.225 Category Assertions

⇒ “notitle” (ugCategoriesCorrectnessPage) 15.0.217 on page 2725

⇒ “notitle” (ugCategoriesConditionalsPage) 15.0.220 on page 2732

```

<ug13.ht>+≡
  \begin{page}{ugDomainsAssertionsPage}{13.3. Category Assertions}
  \beginscroll
  %

```

The `\it Category Assertions` part of your domain constructor definition lists those categories of which all domains created by the constructor are unconditionally members. The word “unconditionally” means that membership in a category does not depend on the values of the parameters to the domain constructor. This part thus defines the link between the domains and the category hierarchies given on the inside covers of this book. As described in `\downlink{‘‘Correctness’’}{ugCategoriesCorrectnessPage}` in Section 12.8`\ignore{ugCategoriesCorrectness}`, it is this link that makes it possible for you to pass objects of the domains as arguments to other operations in Axiom.

Every `\axiomType{QuadraticForm}` domain is declared to be unconditionally a member of category `\axiomType{AbelianGroup}`. An abelian group is a collection of elements closed under addition. Every object `\it x` of an abelian group has an additive inverse `\it y` such that `\texht{$x + y = 0$}``\axiom{{\it x} + {\it y} = 0}`. The exports of an abelian group include `\axiom{0}`, `\axiomOp{+}`, `\axiomOp{-}`, and scalar multiplication by an integer. After asserting that `\axiomType{QuadraticForm}` domains are abelian groups, it is possible to pass quadratic forms to algorithms that only assume arguments to have these abelian group properties.

In `\downlink{‘‘Conditionals’’}{ugCategoriesConditionalsPage}` in Section 12.11`\ignore{ugCategoriesConditionals}`, you saw that `\axiomType{Fraction(R)}`, a member of `\axiomType{QuotientFieldCategory(R)}`, is a member of `\axiomType{OrderedSet}` if `\axiom{R}` is a member of `\axiomType{OrderedSet}`. Likewise, from the `\tt Exports` part of the definition of `\axiomType{ModMonic(R, S)}`, `\begin{verbatim}`
 UnivariatePolynomialCategory(R) with
 if R has Finite then Finite
 ...
`\end{verbatim}`

you see that `\axiomType{ModMonic(R, S)}` is a member of `\axiomType{Finite}` is `\axiom{R}` is.

The `{\tt Exports}` part of a domain definition is the same kind of expression that can appear to the right of an `\axiomSyntax{==}` in a category definition. If a domain constructor is unconditionally a member of two or more categories, a `\axiom{Join}` form is used.

`\spadkey{Join}` The `{\tt Exports}` part of the definition of `\axiomType{FlexibleArray(S)}` reads, for example:

```
\begin{verbatim}
Join(ExtensibleLinearAggregate(S),
      OneDimensionalArrayAggregate(S)) with...
\end{verbatim}
```

```

The `\Browse{}` facility of Hyperdoc is useful for investigating the properties of domains, packages, and categories. From the main Hyperdoc menu, move your mouse to `{\bf Browse}` and click on the left mouse button. This brings up the `\Browse{}` first page. Now, with your mouse pointer somewhere in this window, enter the string ‘‘quadraticform’’ into the input area (all lower case letters will do). Move your mouse to `{\bf Constructors}` and click. Up comes a page describing `\axiomType{QuadraticForm}`.

From here, click on `{\bf Description}`. This gives you a page that includes a part labeled by ‘‘`{\it Description:}`’’. You also see the types for arguments `\axiom{n}` and `\axiom{K}` displayed as well as the fact that `\axiomType{QuadraticForm}` returns an `\axiomType{AbelianGroup}`. You can go and experiment a bit by selecting `{\bf Field}` with your mouse. Eventually, use `\UpButton{}` several times to return to the first page on `\axiomType{QuadraticForm}`.

Select `{\bf Operations}` to get a list of operations for `\axiomType{QuadraticForm}`. You can select an operation by clicking on it to get an individual page with information about that operation. Or you can select the buttons along the bottom to see alternative views or get additional information on the operations. Then return to the page on `\axiomType{QuadraticForm}`.

Select `{\bf Cross Reference}` to get another menu. This menu has buttons for `{\bf Parents}`, `{\bf Ancestors}`, and others. Clicking on `{\bf Parents}`, you see that `\axiomType{QuadraticForm}` has one parent `\axiomType{AbelianMonoid}`.

16.0.228 Representation

⇒ “notitle” (ugDomainsDemoPage) 16.0.226 on page 2745

`<ug13.ht>+≡`

```
\begin{page}{ugDomainsRepPage}{13.6. Representation}
```

```
\beginscroll
```

```
%
```

The `\tt Implementation` part of an Axiom capsule for a domain constructor uses the special variable `\axiom{Rep}` to identify the lower level data type used to represent the objects of the domain.

The `\axiom{Rep}` for quadratic forms is `\axiomType{SquareMatrix(n, K)}`.

This means that all objects of the domain are required to be `\axiom{n}` by `\axiom{n}` matrices with elements from `\axiomType{K}`.

The code for `\axiomFun{quadraticForm}` in Figure `\ref{fig-quadform}` on page `\pageref{fig-quadform}` checks that the matrix is symmetric and then converts it to `\axiomSyntax{\$}`, which means, as usual, “this domain.” Such explicit conversions `\index{conversion}` are generally required by the compiler. Aside from checking that the matrix is symmetric, the code for this function essentially does nothing. The `\frenchspacing\tt m :: \$` on line 28 coerces `\axiom{m}` to a quadratic form. In fact, the quadratic form you created in step (3) of `\downlink{‘‘A Demo’’}{ugDomainsDemoPage}` in Section 13.4`\ignore{ugDomainsDemo}` is just the matrix you passed it in disguise! Without seeing this definition, you would not know that. Nor can you take advantage of this fact now that you do know! When we try in the next step of `\downlink{‘‘A Demo’’}{ugDomainsDemoPage}` in Section 13.4`\ignore{ugDomainsDemo}` to regard `\axiom{q}` as a matrix by asking for `\axiomFun{nrows}`, the number of its rows, Axiom gives you an error message saying, in effect, “Good try, but this won’t work!”

The definition for the `\spadfunFrom{matrix}{QuadraticForm}` function could hardly be simpler:

it just returns its argument after explicitly

```
\spadglossSee{coercing}{coerce} its argument to a matrix.
```

Since the argument is already a matrix, this coercion does no computation.

Within the context of a capsule, an object of `\axiomSyntax{\$}` is regarded both as a quadratic form `\it and` as a matrix.`\footnote{In case each of \axiomSyntax{\$} and \axiom{Rep}`

have the same named operation available,
the one from `\axiom{\$}` takes precedence.
Thus, if you want the one from `\axiomSyntax{Rep}`, you must
package call it using a `\axiomSyntax{\$Rep}` suffix.
This makes the definition of `\axiom{q.v}` easy---it
just calls the `\spadfunFrom{dot}{DirectProduct}` product from
`\axiomType{DirectProduct}` to perform the indicated operation.

```

16.0.229 Multiple Representations

⇒ “notitle” (ugTypesUnionsPage) 7.0.46 on page 1846

```

<ug13.ht>+≡
\begin{page}{ugDomainsMultipleRepsPage}{13.7. Multiple Representations}
\beginscroll
%
```

To write functions that implement the operations of a domain, you want to choose the most computationally efficient data structure to represent the elements of your domain.

A classic problem in computer algebra is the optimal choice for an internal representation of polynomials.

If you create a polynomial, say `\texht{$3x^2+ 5$}``{\axiom{3*x**2 + 5}}`, how does Axiom hold this value internally?

There are many ways.

Axiom has nearly a dozen different representations of polynomials, one to suit almost any purpose.

Algorithms for solving polynomial equations work most efficiently with polynomials represented one way, whereas those for factoring polynomials are most efficient using another.

One often-used representation is a list of terms, each term consisting of exponent-coefficient records written in the order of decreasing exponents.

For example, the polynomial `\texht{$3x^2+5$}``{3*x**2+5}` is

```
%>> I changed the k's in next line to e's as I thought that was
%>> clearer.
```

represented by the list `\axiom{[[e:2, c:3], [e:0, c:5]]}`.

What is the optimal data structure for a matrix?

It depends on the application.

For large sparse matrices, a linked-list structure of records holding only the non-zero elements may be optimal.

If the elements can be defined by a simple formula

```
\texht{$f(i,j)$}{\axiom{f(i,j)}}, then a compiled function for
\axiom{f} may be optimal.
```

Some programmers prefer to represent ordinary matrices as vectors of vectors.

Others prefer to represent matrices by one big linear array where elements are accessed with linearly computable indexes.

While all these simultaneous structures tend to be confusing, Axiom provides a helpful organizational tool for such a purpose:

categories.

`\axiomType{PolynomialCategory}`, for example, provides a uniform user interface across all polynomial types.

Each kind of polynomial implements functions for all these operations, each in its own way.

If you use only the top-level operations in

`\axiomType{PolynomialCategory}` you usually do not care what kind of polynomial implementation is used.

`%>>` I've often thought, though, that it would be nice to be

`%>>` be able to use conditionals for representations.

Within a given domain, however, you define (at most) one representation.^{`\footnote{You can make that representation a`}

`\pspadtype{Union}` type, however. See

`\downlink{'Unions'}{ugTypesUnionsPage}` in Section

2.5^{`\ignore{ugTypesUnions}`} for examples of unions.}

If you want to have multiple representations (that is, several domains, each with its own representation), use a category to describe the `{\tt Exports}`, then define separate domains for each representation.

`\autobuttons`

`\end{page}`

16.0.230 Add Domain

⇒ “notitle” (ugDomainsDemoPage) 16.0.226 on page 2745

```

<ug13.ht>+≡
  \begin{page}{ugDomainsAddDomainPage}{13.8. Add Domain}
  \beginscroll
  %

```

The capsule part of {\tt Implementation} defines functions that implement the operations exported by the domain---usually only some of the operations. In our demo in \downlink{‘‘A Demo’’}{ugDomainsDemoPage} in Section 13.4\ignore{ugDomainsDemo}, we asked for the value of \axiom{3*q-q+q}. Where do the operations \axiomOp{*}, \axiomOp{+}, and \axiomOp{-} come from? There is no definition for them in the capsule!

The {\tt Implementation} part of a definition can optionally specify an ‘‘add-domain’’ to the left of an {\tt add} \spadkey{add} (for \axiomType{QuadraticForm}, defines \axiomType{SquareMatrix(n,K)} is the add-domain). The meaning of an add-domain is simply this: if the capsule part of the {\tt Implementation} does not supply a function for an operation, Axiom goes to the add-domain to find the function. So do \axiomOpFrom{*}{QuadraticForm}, \axiomOpFrom{+}{QuadraticForm} and \axiomOpFrom{-}{QuadraticForm} come from \axiomType{SquareMatrix(n,K)}?

```

\endscroll
\autobuttons
\end{page}

```

16.0.231 Defaults

⇒ “notitle” (ugPackagesPage) 14.0.198 on page 2677

⇒ “notitle” (ugCategoriesDefaultsPage) 15.0.215 on page 2721

(ug13.ht)+≡

```
\begin{page}{ugDomainsDefaultsPage}{13.9. Defaults}
\beginscroll
%
In \downlink{‘‘Packages’’}{ugPackagesPage} in
Chapter 11\ignore{ugPackages}, we saw that
categories can provide
default implementations for their operations.
How and when are they used?
When Axiom finds that \axiomType{QuadraticForm(2, Fraction Integer)}
does not implement the operations \axiomOp{*},
\axiomOp{+}, and \axiomOp{-}, it goes to
\axiomType{SquareMatrix(2,Fraction Integer)} to find it.
As it turns out, \axiomType{SquareMatrix(2, Fraction Integer)} does
not implement {\it any} of these operations!
```

What does Axiom do then? Here is its overall strategy. First, Axiom looks for a function in the capsule for the domain. If it is not there, Axiom looks in the add-domain for the operation. If that fails, Axiom searches the add-domain of the add-domain, and so on. If all those fail, it then searches the default packages for the categories of which the domain is a member. In the case of \axiomType{QuadraticForm}, it searches \axiomType{AbelianGroup}, then its parents, grandparents, and so on. If this fails, it then searches the default packages of the add-domain. Whenever a function is found, the search stops immediately and the function is returned. When all fails, the system calls \axiomFun{error} to report this unfortunate news to you. To find out the actual order of constructors searched for \axiomType{QuadraticForm}, consult \Browse{}: from the \axiomType{QuadraticForm}, click on {\bf Cross Reference}, then on {\bf Lineage}.

Let’s apply this search strategy for our example \axiom{3*q-q+q}. The scalar multiplication comes first. Axiom finds a default implementation in \axiomType{AbelianGroup\&}. Remember from \downlink{‘‘Defaults’’}{ugCategoriesDefaultsPage} in Section 12.6\ignore{ugCategoriesDefaults} that \axiomType{SemiGroup} provides a default definition for \texht{\$x^n\$}{x**n} by repeated squaring? \axiomType{AbelianGroup} similarly provides a definition for \texht{\$n x\$}{n*x} by repeated

doubling.

But the search of the defaults for `\axiomType{QuadraticForm}` fails to find any `\axiomOp{+}` or `\axiomOp{*}` in the default packages for the ancestors of `\axiomType{QuadraticForm}`. So it now searches among those for `\axiomType{SquareMatrix}`. Category `\axiomType{MatrixCategory}`, which provides a uniform interface for all matrix domains, is a grandparent of `\axiomType{SquareMatrix}` and has a capsule defining many functions for matrices, including matrix addition, subtraction, and scalar multiplication. The default package `\axiomType{MatrixCategory\&}` is where the functions for `\axiomOpFrom{+}{QuadraticForm}` and `\spadfunFrom{-}{QuadraticForm}` come from.

You can use `\Browse{}` to discover where the operations for `\axiomType{QuadraticForm}` are implemented. First, get the page describing `\axiomType{QuadraticForm}`. With your mouse somewhere in this window, type a ‘‘2’’, press the `\texht{\fbox{\bf Tab}}{\bf Tab}` key, and then enter ‘‘Fraction Integer’’ to indicate that you want the domain `\axiomType{QuadraticForm}(2, Fraction Integer)`. Now click on `{\bf Operations}` to get a table of operations and on `\axiomOp{*}` to get a page describing the `\axiomOp{*}` operation. Finally, click on `{\bf implementation}` at the bottom.

```
\endscroll
\autobuttons
\end{page}
```

16.0.232 Origins

```

<ug13.ht>+≡
\begin{page}{ugDomainsOriginsPage}{13.10. Origins}
\beginscroll
%
```

Aside from the notion of where an operation is implemented, a useful notion is the `\it origin` or “home” of an operation. When an operation (such as `\spadfunFrom{quadraticForm}{QuadraticForm}`) is explicitly exported by a domain (such as `\axiomType{QuadraticForm}`), you can say that the origin of that operation is that domain. If an operation is not explicitly exported from a domain, it is inherited from, and has as origin, the (closest) category that explicitly exports it. The operations `\axiomOpFrom{+}{AbelianMonoid}` and `\axiomOpFrom{-}{AbelianMonoid}` of `\axiomType{QuadraticForm}`, for example, are inherited from `\axiomType{AbelianMonoid}`. As it turns out, `\axiomType{AbelianMonoid}` is the origin of virtually every `\axiomOp{+}` operation in Axiom!

Again, you can use `\Browse{}` to discover the origins of operations. From the `\Browse{}` page on `\axiomType{QuadraticForm}`, click on `\bf Operations`, then on `\bf origins` at the bottom of the page.

The origin of the operation is the `\it only` place where on-line documentation is given. However, you can re-export an operation to give it special documentation. Suppose you have just invented the world’s fastest algorithm for inverting matrices using a particular internal representation for matrices. If your matrix domain just declares that it exports `\axiomType{MatrixCategory}`, it exports the `\axiomFun{inverse}` operation, but the documentation the user gets from `\Browse{}` is the standard one from `\axiomType{MatrixCategory}`. To give your version of `\axiomFun{inverse}` the attention it deserves, simply export the operation explicitly with new documentation. This redundancy gives `\axiomFun{inverse}` a new origin and tells `\Browse{}` to present your new documentation.

16.0.233 Short Forms

```
<ug13.ht>+≡
\begin{page}{ugDomainsShortFormsPage}{13.11. Short Forms}
\beginscroll
```

In Axiom, a domain could be defined using only an add-domain and no capsule. Although we talk about rational numbers as quotients of integers, there is no type `\pspadtype{RationalNumber}` in Axiom. To create such a type, you could compile the following ‘‘short-form’’ definition:

```
\beginImportant

\noindent
{\tt 1.\ \ \ RationalNumber()\ \ ==\ Fraction(Integer)}\newline
\endImportant
```

The `{\tt Exports}` part of this definition is missing and is taken to be equivalent to that of `\axiomType{Fraction(Integer)}`. Because of the add-domain philosophy, you get precisely what you want. The effect is to create a little stub of a domain. When a user asks to add two rational numbers, Axiom would ask `\pspadtype{RationalNumber}` for a function implementing this `\axiomOp{+}`. Since the domain has no capsule, the domain then immediately sends its request to `\axiomType{Fraction (Integer)}`.

The short form definition for domains is used to define such domains as `\axiomType{MultivariatePolynomial}`:

```
\beginImportant

\noindent
{\tt 1.\ \ \ MultivariatePolynomial(vl:\ List\ Symbol,\ R:\ Ring)\ ==}
\newline
{\tt 2.\ \ \ \ \ SparseMultivariatePolynomial(R,)\newline
{\tt 3.\ \ \ \ \ \ \ \ OrderedVariableList\ vl)}\newline
\endImportant

\endscroll
\autobuttons
\end{page}
```

16.0.234 Example 1: Clifford Algebra

⇒ “notitle” (CliffordAlgebraXmpPage) 3.15.2 on page 227

```
<ug13.ht>+=
\begin{page}{ugDomainsCliffordPage}{13.12. Example 1: Clifford Algebra}
\beginscroll
%
```

Now that we have `\axiomType{QuadraticForm}` available, let's put it to use. Given some quadratic form Q described by an n by n matrix over a field K , the domain `\axiomType{CliffordAlgebra}(n, K, Q)` defines a vector space of dimension 2^n over K . This is an interesting domain since complex numbers, quaternions, exterior algebras and spin algebras are all examples of Clifford algebras.

The basic idea is this: the quadratic form Q defines a basis $\{e_1, e_2, \dots, e_n\}$ for the vector space K^n --- the direct product of K with itself n times. From this, the Clifford algebra generates a basis of 2^n elements given by all the possible products of the e_i in order without duplicates, that is, $\{1, e_1, e_2, e_1e_2, e_3, e_1e_3, e_2e_3, e_1e_2e_3, \dots\}$ and so on.

The algebra is defined by the relations

```
\begin{verbatim}
ei*ei = Q(ei)
ei*ej = -ej*ei,  i ^= j
\end{verbatim}
```

Now look at the snapshot of its definition given in Figure

Line 18 defines `\axiom{New}` as shorthand for the more lengthy expression `\axiom{new(dim, 0\{K\})\$Rep}`, which computes a primitive array of length `\texht{2^n}{2**n}` filled with `\axiom{0}`'s from domain `\axiom{K}`.

The types of all local functions must be declared.

```
\ignore{CliffordAlgebra}.
```

\end{page}

ug13.ht+≡

```
\begin{page}{ugDomsinsDatabasePage}
{13.13. Example 2: Building A Query Facility}
\beginscroll
%
```

We now turn to an entirely different kind of application,
 building a query language for a database.

Here is the practical problem to solve.

The `\Browse{}` facility of Axiom has a
 database for all operations and constructors which is
 stored on disk and accessed by Hyperdoc.

For our purposes here, we regard each line of this file as having
 eight fields:

`{\tt class, name, type, nargs, exposed, kind, origin,}` and `{\tt condition.}`
 Here is an example entry:

```
\begin{verbatim}
o'determinant'$->R'1'x'd'Matrix(R)'has(R,commutative("*"))
\end{verbatim}
```

In English, the entry means:

```
\texht{\begin{quotation}}{\newline}
\texht{\raggedright}{}
```

The operation `\axiomFun{determinant}`: `\spadsig{\$}{R}` with `{\it 1}`
 argument, is

```
{\it exposed} and is exported by {\it domain} \axiomType{Matrix(R)}
if {\tt R has commutative("*")}.
\texht{\end{quotation}}{\newline}
```

Our task is to create a little query language that allows us
 to get useful information from this database.

```

\end{page}
```

16.0.236 A Little Query Language

```

<ug13.ht>+≡
\begin{page}{ugDomainsQueryLanguagePage}{13.13.1. A Little Query Language}
\beginscroll

```

First we design a simple language for accessing information from the database.

We have the following simple model in mind for its design.

Think of the database as a box of index cards.

There is only one search operation---it

takes the name of a field and a predicate

(a boolean-valued function) defined on the fields of the index cards.

When applied, the search operation goes through the entire box selecting only those index cards for which the predicate is true.

The result of a search is a new box of index cards.

This process can be repeated again and again.

The predicates all have a particularly simple form: `{\it symbol} {\tt =} {\it pattern}`, where `{\it symbol}` designates one of the fields, and `{\it pattern}` is a ‘‘search string’’---a string that may contain a ‘‘`{\tt *}`’’ as a wildcard.

Wildcards match any substring, including the empty string.

Thus the pattern `{\tt "ma*t"}` matches

`{\tt "mat", "doormat"}` and `{\tt "smart"}`.

To illustrate how queries are given, we give you a sneak preview of the facility we are about to create.

```

\xtc{
Extract the database of all Axiom operations.
}{
\spadpaste{ops := getDatabase("o")\bound{o1}}
}
\xtc{
How many exposed three-argument \axiomFun{map} operations involving
streams?
}{
\spadpaste{ops.(name="map").(nargs="3").(type="*Stream*")}
\bound{o2}\free{o1}}
}

```

As usual, the arguments of `\axiomFun{elt}` (`\axiomSyntax{.}`) associate to the left.

The first `\axiomFun{elt}` produces the set of all operations with name `{\tt map}`.

The second `\axiomFun{elt}` produces the set of all map operations with three arguments.

The third `\axiomFun{elt}` produces the set of all three-argument map operations having a type mentioning `\axiomType{Stream}`.

Another thing we'd like to do is to extract one field from each of the index cards in the box and look at the result.

Here is an example of that kind of request.

```
\xctc{
What constructors explicitly export a \axiomFun{determinant} operation?
}{
\spadpaste{
elt(elt(elt(elt(ops,name="determinant"),origin),sort),unique)\free{o1}}
}
```

The first `\axiomFun{elt}` produces the set of all index cards with name `{\tt determinant}`.

The second `\axiomFun{elt}` extracts the `{\tt origin}` component from each index card. Each origin component is the name of a constructor which directly exports the operation represented by the index card.

Extracting a component from each index card produces what we call a `{\it datalist}`.

The third `\axiomFun{elt}`, `{\tt sort}`, causes the datalist of origins to be sorted in alphabetic order.

The fourth, `{\tt unique}`, causes duplicates to be removed.

Before giving you a more extensive demo of this facility, we now build the necessary domains and packages to implement it.
%We will introduce a few of our minor conveniences.

16.0.237 The Database Constructor

(ug13.ht)+≡

```
\begin{page}{ugDomainsDatabaseConstructorPage}
{13.13.2. The Database Constructor}
\beginscroll
```

We work from the top down. First, we define a database, our box of index cards, as an abstract datatype. For sake of illustration and generality, we assume that an index card is some type $\text{\texttt{axiom}\{S\}}$, and that a database is a box of objects of type $\text{\texttt{axiom}\{S\}}$. Here is the Axiom program defining the $\text{\texttt{pspadtype}\{Database\}}$ domain.

```
\beginImportant

\noindent
{\tt 1.\ \ \ \ PI\ ==>\ PositiveInteger}\newline
{\tt 2.\ \ \ \ Database(S):\ Exports\ ==\ Implementation\ where}\newline
{\tt 3.\ \ \ \ \ S:\ Object\ with\ }\newline
{\tt 4.\ \ \ \ \ \ \ \ elt:\ (\$, \ Symbol)\ ->\ String}\newline
{\tt 5.\ \ \ \ \ \ \ \ display:\ \$\ ->\ Void}\newline
{\tt 6.\ \ \ \ \ \ \ \ fullDisplay:\ \$\ ->\ Void}\newline
{\tt 7.\ \ \ \ }\newline
{\tt 8.\ \ \ \ \ Exports\ ==\ with}\newline
{\tt 9.\ \ \ \ \ \ \ \ elt:\ (\$,QueryEquation)\ ->\ \$}\newline
{\tt 10.\ \ \ \ \ \ \ \ elt:\ (\$, \ Symbol)\ ->\ DataList\ String}\newline
{\tt 11.\ \ \ \ \ \ \ \ "+":\ (\$, \$)\ ->\ \$}\newline
{\tt 12.\ \ \ \ \ \ \ \ "-":\ (\$, \$)\ ->\ \$}\newline
{\tt 13.\ \ \ \ \ \ \ \ display:\ \$\ ->\ Void}\newline
{\tt 14.\ \ \ \ \ \ \ \ fullDisplay:\ \$\ ->\ Void}\newline
{\tt 15.\ \ \ \ \ \ \ \ fullDisplay:\ (\$,PI,PI)\ ->\ Void}\newline
{\tt 16.\ \ \ \ \ \ \ \ coerce:\ \$\ ->\ OutputForm}\newline
{\tt 17.\ \ \ \ \ Implementation\ ==\ add}\newline
{\tt 18.\ \ \ \ \ \ \ \ \ \ \ \ \ \ ...}\newline
\endImportant
```

The domain constructor takes a parameter $\text{\texttt{axiom}\{S\}}$, which stands for the class of index cards. We describe an index card later. Here think of an index card as a string which has the eight fields mentioned above.

First, we tell Axiom what operations we are going to require from index cards.

Next, we tell Axiom what operations the user can apply to the database.

This part defines our little query language.

The most important operation is

`{\frenchspacing\tt db . field = pattern}` which returns a new database, consisting of all index cards of `{\tt db}` such that the `\axiom{field}` part of the index card is matched by the string pattern called `\axiom{pattern}`.

The expression `{\tt field = pattern}` is an object of type `\axiomType{QueryEquation}` (defined in the next section).

The `\tt Implementation` part of `\axiomType{Database}` is straightforward.

\beginImportant

```
\noindent
{\tt 1.\ \ \ \ \ Implementation\ ==\ add}\newline
{\tt 2.\ \ \ \ \ \ \ s:\ Symbol}\newline
{\tt 3.\ \ \ \ \ \ \ Rep\ :=\ List\ S}\newline
{\tt 4.\ \ \ \ \ \ \ elt(db,equation)\ ==\ ...}\newline
{\tt 5.\ \ \ \ \ \ \ }
elt(db,key)\ ==\ [x.key\ for\ x\ in\ db]:DataList(String)}\newline
{\tt 6.\ \ \ \ \ \ }
```

```
\endscroll
\autobuttons
\end{page}
```

16.0.238 Query Equations

<ug13.ht>+≡

```
\begin{page}{ugDomainsQueryEquationsPage}{13.13.3. Query Equations}
\beginscroll
```

The predicate for our search is given by an object of type
`\pspadtype{QueryEquation}`.
 Axiom does not have such an object yet so we
 have to invent it.

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ QueryEquation():\ Exports\ ==\ Implementation\ where}\newline
{\tt 2.\ \ \ \ \ Exports\ ==\ with}\newline
{\tt 3.\ \ \ \ \ \ equation:\ (Symbol,\ String)\ ->\ \$}\newline
{\tt 4.\ \ \ \ \ \ variable:\ \$\ ->\ Symbol}\newline
{\tt 5.\ \ \ \ \ \ value:\ \ \ \ \ \$\ ->\ String}\newline
{\tt 6.\ \ \ \ }\newline
{\tt 7.\ \ \ \ \ Implementation\ ==\ add}\newline
{\tt 8.\ \ \ \ \ \ Rep\ :=\ Record(var:Symbol,\ val:String)}\newline
{\tt 9.\ \ \ \ \ \ equation(x,\ s)\ ==\ [x,\ s]}\newline
{\tt 10.\ \ \ \ \ \ variable\ q\ ==\ q.var}\newline
{\tt 11.\ \ \ \ \ \ value\ \ \ \ \ q\ ==\ q.val}\newline
\endImportant
```

Axiom converts an input expression of the form
`\axiom{{\it a} = {\it b}}` to `\axiom{equation({\it a}, {\it b})}`.
 Our equations always have a symbol on the left and a string
 on the right.

The `{\tt Exports}` part thus specifies an operation
`\axiomFun{equation}` to create a query equation, and
`\pspadfun{variable}` and `\pspadfun{value}` to select the left- and
 right-hand sides.

The `{\tt Implementation}` part uses `\pspadtype{Record}` for a
 space-efficient representation of an equation.

Here is the missing definition for the `\axiomFun{elt}` function of
`\pspadtype{Database}` in the last section:

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ \ \ \ elt(db,eq)\ ==}\newline
{\tt 2.\ \ \ \ \ \ field\ \ \ :=\ variable\ eq}\newline
```

```
{\tt 3.\ \ \ \ \ \ \ \ value\ :=\ value\ eq}\newline
{\tt 4.\ \ \ \ \ \ \ \ \
[x\ for\ x\ in\ db\ |\ matches?(value,x.field)]}\newline
\endImportant
```

Recall that a database is represented by a list.
 Line 4 simply runs over that list collecting all elements
 such that the pattern (that is, `\axiom{value}`)
 matches the selected field of the element.

```
\endscroll
\autobuttons
\end{page}
```

16.0.239 DataLists

<ug13.ht>+≡

```
\begin{page}{ugDomainsDataListsPage}{13.13.4. DataLists}
\beginscroll
```

Type `\pspadtype{DataList}` is a new type invented to hold the result of selecting one field from each of the index cards in the box. It is useful to make datalists extensions of lists---lists that have special `\axiomFun{elt}` operations defined on them for sorting and removing duplicates.

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ DataList(S:OrderedSet)\ :\ Exports\ ==\
Implementation\ where}\newline
{\tt 2.\ \ \ \ \ Exports\ ==\ ListAggregate(S)\ with}\newline
{\tt 3.\ \ \ \ \ \ \ elt:\ (\$, "unique")\ ->\ \$}\newline
{\tt 4.\ \ \ \ \ \ \ elt:\ (\$, "sort")\ ->\ \$}\newline
{\tt 5.\ \ \ \ \ \ \ elt:\ (\$, "count")\ ->\ NonNegativeInteger}\newline
{\tt 6.\ \ \ \ \ \ \ coerce:\ List\ S\ ->\ \$}\newline
{\tt 7.\ \ \ \ }\newline
{\tt 8.\ \ \ \ \ Implementation\ ==\ \ List(S)\ add}\newline
{\tt 9.\ \ \ \ \ \ \ Rep\ :=\ List\ S}\newline
{\tt 10.\ \ \ \ \ \ \ elt(x, "unique")\ ==\ removeDuplicates(x)}\newline
{\tt 11.\ \ \ \ \ \ \ elt(x, "sort")\ ==\ sort(x)}\newline
{\tt 12.\ \ \ \ \ \ \ elt(x, "count")\ ==\ \#x}\newline
{\tt 13.\ \ \ \ \ \ \ coerce(x:List\ S)\ ==\ x\ ::\ \$}\newline
\endImportant
```

The `{\tt Exports}` part asserts that datalists belong to the category `\axiomType{ListAggregate}`.

Therefore, you can use all the usual list operations on datalists, such as `\spadfunFrom{first}{List}`, `\spadfunFrom{rest}{List}`, and `\spadfunFrom{concat}{List}`.

In addition, datalists have four explicit operations.

Besides the three `\axiomFun{elt}` operations, there is a `\axiomFun{coerce}` operation that creates datalists from lists.

The `{\tt Implementation}` part needs only to define four functions. All the rest are obtained from `\axiomType{List(S)}`.

```
\endscroll
\autobuttons
\end{page}
```

16.0.240 Index Cards

<ug13.ht>+≡

```
\begin{page}{ugDomainsDatabasePage}{13.13.5. Index Cards}
\beginscroll
```

An index card comes from a file as one long string. We define functions that extract substrings from the long string. Each field has a name that is passed as a second argument to `\axiomFun{elt}`.

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ \ IndexCard()\ ==\ Implementation\ where}\newline
{\tt 2.\ \ \ \ \ Exports\ ==\ with}\newline
{\tt 3.\ \ \ \ \ \ \ \ elt:\ (\$, \ Symbol)\ ->\ String}\newline
{\tt 4.\ \ \ \ \ \ \ \ display:\ \$\ ->\ Void}\newline
{\tt 5.\ \ \ \ \ \ \ \ fullDisplay:\ \$\ ->\ Void}\newline
{\tt 6.\ \ \ \ \ \ \ \ coerce:\ String\ ->\ \$}\newline
{\tt 7.\ \ \ \ \ \ Implementation\ ==\ String\ add\ ...}\newline
\endImportant
```

We leave the `{\tt Implementation}` part to the reader.
All operations involve straightforward string manipulations.

```
\endscroll
\autobuttons
\end{page}
```

16.0.241 Creating a Database

<ug13.ht>+≡

```
\begin{page}{ugDomainsCreatingPage}{13.13.6. Creating a Database}
\beginscroll
```

We must not forget one important operation: one that builds the database in the first place! We'll name it `\pspadfun{getDatabase}` and put it in a package. This function is implemented by calling the `\Lisp{}` function `\axiom{getBrowseDatabase(s)}` to get appropriate information from `\Browse{}`. This operation takes a string indicating which lines you want from the database: `\axiom{"o"}` gives you all operation lines, and `\axiom{"k"}`, all constructor lines. Similarly, `\axiom{"c"}`, `\axiom{"d"}`, and `\axiom{"p"}` give you all category, domain and package lines respectively.

```
\beginImportant
```

```
\noindent
{\tt 1.\ \ \ OperationsQuery():\ Exports\ ==\ Implementation\ where}
\newline
{\tt 2.\ \ \ \ \ Exports\ ==\ with}\newline
{\tt 3.\ \ \ \ \ \ \ getDatabase:\ String\ ->\ Database(IndexCard)}
\newline
{\tt 4.\ \ \ \ }\newline
{\tt 5.\ \ \ \ \ Implementation\ ==\ add}\newline
{\tt 6.\ \ \ \ \ \ \ getDatabase(s)\ ==\ getBrowseDatabase(s)\$Lisp}
\newline
\endImportant
```

We do not bother creating a special name for databases of index cards.

`\pspadtype{Database (IndexCard)}` will do.

Notice that we used the package `\pspadtype{OperationsQuery}` to create, in effect,

a new kind of domain: `\pspadtype{Database(IndexCard)}`.

```
\endscroll
```

```
\autobuttons
```

```
\end{page}
```

16.0.242 Putting It All Together

(ug13.ht)+≡

```
\begin{page}{ugDomainsPuttingPage}{13.13.7. Putting It All Together}
\beginscroll
```

To create the database facility, you put all these constructors into one file. \footnote{You could use separate files, but we are putting them all together because, organizationally, that is the logical thing to do.}

At the top of the file put \spadcmd{abbrev} commands, giving the constructor abbreviations you created.

```
\beginImportant
```

```
\noindent
```

```
{\tt 1.\ \ \ )abbrev\ domain\ \ ICARD\ \ \ IndexCard}\newline
{\tt 2.\ \ \ )abbrev\ domain\ \ QEQAT\ \ QueryEquation}\newline
{\tt 3.\ \ \ )abbrev\ domain\ \ MTHING\ \ MergeThing}\newline
{\tt 4.\ \ \ )abbrev\ domain\ \ DLIST\ \ \ DataList}\newline
{\tt 5.\ \ \ )abbrev\ domain\ \ DBASE\ \ \ Database}\newline
{\tt 6.\ \ \ )abbrev\ package\ OPQUERY\ OperationsQuery}\newline
\endImportant
```

With all this in {\bf alql.spad}, for example, compile it using

```
\begin{verbatim}
```

```
)compile alql
```

```
\end{verbatim}
```

and then load each of the constructors:

```
\begin{verbatim}
```

```
)load ICARD QEQAT MTHING DLIST DBASE OPQUERY
```

```
\end{verbatim}
```

You are ready to try some sample queries.

```
\endscroll
```

```
\autobuttons
```

```
\end{page}
```

16.0.243 Example Queries

<ug13.ht>+≡

```
\begin{page}{ugDomainsExamplesPage}{13.13.8. Example Queries}
\beginscroll
```

Our first set of queries give some statistics on constructors in the current Axiom system.

```
\xtc{
How many constructors does Axiom have?
}{
\spadpaste{ks := getDatabase "k"\bound{q1}}
}
\xtc{
Break this down into the number of categories, domains, and packages.
}{
\spadpaste{[ks.(kind=k) for k in ["c","d","p"]]\bound{q3}\free{q1}}
}
\xtc{
What are all the domain constructors that take no parameters?
}{
\spadpaste{elt(ks.(kind="d").(nargs="0"),name)\bound{q4}\free{q1}}
}
\xtc{
How many constructors have ‘‘Matrix’’ in their name?
}{
\spadpaste{mk := ks.(name="*Matrix*")\bound{q5}\free{q1}}
}
\xtc{
What are the names of those that are domains?
}{
\spadpaste{elt(mk.(kind="d"),name)\bound{q6}\free{q5}}
}
\xtc{
How many operations are there in the library?
}{
\spadpaste{o := getDatabase "o"\bound{o1}}
}
\xtc{
Break this down into categories, domains, and packages.
}{
\spadpaste{[o.(kind=k) for k in ["c","d","p"]]\free{o1}}
}
}
```

The query language is helpful in getting information about a

particular operation you might like to apply.
 While this information can be obtained with
`\Browse{}`, the use of the query database gives you data that you
 can manipulate in the workspace.

```
\xtc{
How many operations have ‘eigen’ in the name?
}{
\spadpaste{eigens := o.(name="*eigen*")\bound{eigens}\free{o1}}
}
\xtc{
What are their names?
}{
\spadpaste{elt(eigens,name)\free{eigens}}
}
\xtc{
Where do they come from?
}{
\spadpaste{elt(elt(elt(eigens,origin),sort),unique) \free{eigens}}
}
```

The operations `\axiomOp{+}` and `\axiomOp{-}` are useful for
 constructing small databases and combining them.
 However, remember that the only matching you can do is string
 matching.
 Thus a pattern such as `{\tt "*Matrix*"}` on the type field
 matches
 any type containing `\axiomType{Matrix}`, `\axiomType{MatrixCategory}`,
`\axiomType{SquareMatrix}`, and so on.

```
\xtc{
How many operations mention ‘Matrix’ in their type?
}{
\spadpaste{tm := o.(type="*Matrix*")\bound{x10}\free{o1}}
}
\xtc{
How many operations come from constructors with ‘Matrix’ in
their name?
}{
\spadpaste{fm := o.(origin="*Matrix*")\bound{x11}\free{o1}}
}
\xtc{
How many operations are in \axiom{fm} but not in \axiom{tm}?
}{
\spadpaste{fm-tm \bound{x12}\free{x10 x11}}
}
```

```

\xtc{
Display the operations that both mention ‘‘Matrix’’ in their type
